The Microsoft component uses the list of indicated entries to report the BSS list to the operation system. It is also used to populate parameters for roam and connect tasks.

Get property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SSID			The SSID that the host needs the BSS list update for.

Get property results

No additional data. The data in the header is sufficient.

Unsolicited indication

NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_NEXT_ACTION_FRAME_DIALOG_TOKEN

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_GET_NEXT_ACTION_FRAME_DIALOG_TOKEN requests the DialogToken to be used in the next Action frame.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_NEXT_DIALOG_TOKEN			A dialog token.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_PM_PROTOCOL_OFFLOAD

Article • 03/14/2023

OID_WDI_GET_PM_PROTOCOL_OFFLOAD requests a list of protocol offloads for power management.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Not applicable	1

Get property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PM_PROTOCOL_OFFLOAD_GET			Protocol offload ID.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv4ARP		X	IPv4 ARP protocol offload parameters.
WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv6NS		X	IPv6 NS protocol offload parameters.
WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY		X	RSN Rekey protocol offload parameters.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

See also

OID_WDI_GET_RECEIVE_COALESCING_MATCH_COUNT

Article • 03/14/2023

OID_WDI_GET_RECEIVE_COALESCING_MATCH_COUNT requests the number of packets that have matched receive filters on the network port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_COALESCING_FILTER_MATCH_COUNT			The number of packets that have matched receive filters on the network port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_STATISTICS

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_GET_STATISTICS requests that the IHV component returns MAC and PHY layer statistics.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Set not supported	1

The MAC statistics must all be maintained per port. PHY statistics must also be maintained per port unless exempted. If PHY statistics cannot be maintained per port (as allowed by exemption), the statistics can be maintained per "channel" (PHY statistics for two ports operating on the same channel can be combined).

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_MAC_STATISTICS	X		Per-peer MAC statistics.
WDI_TLV_PHY_STATISTICS	X		Per-port PHY statistics.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_SUPPORTED_DEVICE_SERVICES

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_GET_SUPPORTED_DEVICE_SERVICES queries the IHV driver for all of its supported device services (with each device service identified by a GUID). If no device services are supported, LE should fail the command with **STATUS_NOT_SUPPORTED**.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

WLAN will provide a pipeline for any user mode component (UMDF driver or UM service) to communicate with the IHV WLAN driver. Among other things, this pipeline can be used for engaging SAR scenarios by being the platform to send information between the OEM sensors and the IHV firmware. The definition/format of the data to be sent to the IHV/LE driver and what the commands must do is not specified by UE. All contracts with the IHV must be defined by the OEM, and the device service WDI commands (and the corresponding user mode WLAN APIs) will just serve as a generic pipeline.

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DEVICE_SERVICE_GUID_LIST			The list of device services that the underlying IHV driver exposes to UM components.

Requirements

Requirement	Value
Minimum supported client	Windows 11
Minimum supported server	Windows Server 2022
Header	Dot11wdi.h

OID_WDI_IHV_REQUEST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_IHV_REQUEST is used to forward information that an IHV extensibility module has sent to the miniport.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

This command is not serialized with any tasks. It is serialized with other properties and with the M1-M3 of a task.

Command parameter

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_IHV_DATA		X	The information from the IHV extensibility module.

Response result

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_IHV_DATA		X	The response to be sent to the IHV extensibility module. The data value is forwarded as-is to the IHV extensibility module.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_ADAPTER_CONFIGURATION

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_ADAPTER_CONFIGURATION configures the adapter. It is an optional property and can only be sent before any ports are created.

Scope	Set serialized with task	Normal execution time (seconds)
Adapter	Yes	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONFIGURED_MAC_ADDRESS		X	MAC address.
WDI_TLV_UNREACHABLE_DETECTION_THRESHOLD		X	Unreachable detection threshold.
WDI_TLV_P2P_GO_INTERNAL_RESET_POLICY		X	Policy used by the firmware for operating channel selection after a Wi-Fi Direct GO Reset is stopped/restarted.
WDI_TLV_BAND_ID_LIST		X	List of band IDs.
WDI_TLV_LINK_QUALITY_BAR_MAP			Mapping of signal quality to Wi-Fi signal strength bars. This field should be ignored by the adapter and it should use the behavior specified in NDIS_STATUS_WDI_INDICATION_LINK_STATE_CHANGE for doing Link Quality notifications.
WDI_TLV_ADAPTER_NLO_SCAN_MODE		X	Indicates whether the NLO scans should be performed in active or passive mode.
WDI_TLV_PLDR_SUPPORT			Added in Windows 10, version 1511, WDI version 1.0.10. Specifies if PLDR is supported.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_ADD_CIPHER_KEYS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_ADD_CIPHER_KEYS adds or overwrites cipher keys in the key table of a port. This is a set-only property.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Cipher keys that are marked as Static should not be cleared on a roam. They can only be cleared on a OID_WDI_TASK_DOT11_RESET or if they are overwritten with a new OID_WDI_SET_ADD_CIPHER_KEYS.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SET_CIPHER_KEY_INFO	X		The cipher keys to be added or overwritten in the key table of the port.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Dot11wdi.h

OID_WDI_SET_ADD_PM_PROTOCOL_OFFLOAD

Article • 03/14/2023

OID_WDI_SET_ADD_PM_PROTOCOL_OFFLOAD adds a list of one or more protocol offloads for power management.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

This property provides information to enable the device/firmware to implement these protocols while the main CPU is asleep. In this state, the firmware and device handles the offloaded tasks without waking up the host.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv4ARP		X	IPv4 ARP protocol offload parameters.
WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv6NS		X	IPv6 NS protocol offload parameters.
WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY		X	RSN Rekey protocol offload parameters.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_ADD_WOL_PATTERN

Article • 03/14/2023

OID_WDI_SET_ADD_WOL_PATTERN adds a wake-on-LAN (WOL) pattern to the firmware.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

The host defines the packet pattern types to add to the firmware. The firmware detects matching packets that arrive in Dx. If detected, the firmware asserts the wake interrupt.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_WAKE_PACKET_BITMAP_PATTERN	X	X	WOL pattern information.
WDI_TLV_WAKE_PACKET_MAGIC_PACKET		X	Pattern ID of the magic packet.
WDI_TLV_WAKE_PACKET_IPv4_TCP_SYNC	X	X	WOL IPv4 TCP sync packet information.
WDI_TLV_WAKE_PACKET_IPv6_TCP_SYNC	X	X	WOL IPv4 TCP sync packet information.
WDI_TLV_WAKE_PACKET_EAPOL_REQUEST_ID_MESSAGE		X	WOL pattern ID of a EAPOL request ID message.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_ADVERTISEMENT_INFORMATION

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_ADVERTISEMENT_INFORMATION configures the Information Elements (IEs) and other advertisement settings to be included in the probe request, probe response, and beacons sent by the specified port. This request is only applicable to Wi-Fi Direct ports.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

When this command is received by the device, it shall update any relevant Wi-Fi Direct IEs, and append any necessary additional IEs in future outgoing messages sent by this port.

Set property parameters

WDI can provide a pre-configured set of prefix hashes for the advertised services. If a peer sends a hash, the driver first tries to match with a service name hash as defined in WDI_TLV_P2P_ADVERTISED_PREFIX_ENTRY. If a match is found from the prefix hashes, the driver searches for the service(s) in WDI_TLV_P2P_ADVERTISED_SERVICE_ENTRY that have the prefix and responds with those. If a match is not found, the driver tries to match the requested service name hash in WDI_TLV_P2P_ADVERTISED_SERVICE_ENTRY.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ADDITIONAL_IES		X	Additional IEs to be included.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_DEVICE_INFO		X	Wi-Fi Direct device information.
WDI_TLV_P2P_DEVICE_CAPABILITY		X	Wi-Fi Direct device capabilities.
WDI_TLV_P2P_GROUP_OWNER_CAPABILITY		X	Wi-Fi Direct Group Owner capability information
WDI_TLV_P2P_SECONDARY_DEVICE_TYPE_LIST		X	List of Wi-Fi Direct secondary device types.
WDI_TLV_P2P_ADVERTISED_SERVICES		X	Wi-Fi Direct advertised services.

Set property results

No additional data. The data in the header is sufficient.

Unsolicited indication

NDIS_STATUS_WDI_INDICATION_ACTION_FRAME_RECEIVED The adapter must indicate ANQP Action Frame requests for the Service Information if it receives an ANQP request (or any other unknown action frame) from a peer.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_ASSOCIATION_PARAMETERS

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_ASSOCIATION_PARAMETERS specifies parameters that the adapter can use during association to a set of BSSIDs.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

This command replaces the previously configured list of BSSID-specific association parameters.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONNECT_BSS_ENTRY	X		The BSS entries and parameters.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Dot11wdi.h

OID_WDI_SET_CLEAR_RECEIVE_COALESCING

Article • 03/14/2023

OID_WDI_SET_CLEAR_RECEIVE_COALESCING is used by the host to remove a packet filter for packet coalescing.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SET_CLEAR_RECEIVE_COALESCING			The packet filter ID to be removed.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

See also

OID_WDI_SET_CONNECTION_QUALITY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_CONNECTION_QUALITY provides a hint to the IHV component to enforce connection quality for a given virtualized port. This hint allows the port to optimize channel usage in different scenarios.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Note This property specifies data path quality of service hints, which may cause conflicts with other properties or tasks that are issued to the adapter.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONNECTION_QUALITY_PARAMETERS			The desired Wi-Fi connection quality hint.
WDI_TLV_LOW_LATENCY_CONNECTION_QUALITY_PARAMETERS		X	The behavior for low latency connection quality. This is only required if the connection quality is set to WDI_CONNECTION_QUALITY_LOW_LATENCY.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_DEFAULT_KEY_ID

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_DEFAULT_KEY_ID sets the default key ID for packet transmission on a port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DEFAULT_TX_KEY_ID_PARAMETERS			The default key ID for packet transmission on the port.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_DELETE_CIPHER_KEYS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_DELETE_CIPHER_KEYS deletes cipher keys from the device's cipher key table.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DELETE_CIPHER_KEY_INFO	X		The cipher keys to be deleted from the device's key table.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

See also

OID_WDI_SET_ADD_CIPHER_KEYS

OID_WDI_SET_ENCAPSULATION_OFFLOAD

Article • 03/14/2023

OID_WDI_SET_ENCAPSULATION_OFFLOAD is sent by the OS to indicate that the lower edge driver (LE) should start doing the TCP Checksum/LSO offloads.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

When this message is received, the LE should indicate its current encapsulation offload configuration with NDIS_STATUS_WDI_INDICATION_TASK_OFFLOAD_CURRENT_CONFIG. For receive operations, the LE should not start the checksum offload until after it receives the OID_WDI_SET_ENCAPSULATION_OFFLOAD message.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V4_PARAMETERS			Specifies if IPv4 offloading should be started.
WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V6_PARAMETERS			Specifies if IPv6 offloading should be started.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_END_DWELL_TIME

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_END_DWELL_TIME is typically sent during an Action Frame exchange, either when WDI has to wait some time before sending a followup Action Frame, or when the protocol sequence is complete. This command can be sent on the device port or station port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

On receipt of this command, the firmware can choose to stop dwelling on the channel that had been specified when WDI sent the command to send the Action Frame. If the Dwell Time had already expired, the firmware should ignore this command.

Set property parameters

No additional parameters. The data in the header is sufficient.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

OID_WDI_SET_FAST_BSS_TRANSITION_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_FAST_BSS_TRANSITION_PARAMETERS is sent in response to NDIS_STATUS_WDI_INDICATION_FT_ASSOC_PARAMS_NEEDED. It has the parameters required to send the (Re)Association request. The command is sent to the driver as a direct OID.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_STATUS			If this status is success, the rest of the fields (RSNIE, MDE, FTE) are present. This indicates that there are no problems or errors with the Authentication response (for example, MIC check failure) and the IHV can proceed with the reassociation request.
WDI_TLV_FT_RSNIE		X	The RSN IE byte blob.
WDI_TLV_FT_MDE		X	The MDE byte blob.
WDI_TLV_FT_FTE		X	The FTE byte blob.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_FLUSH_BSS_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_FLUSH_BSS_ENTRY is sent to the device to flush the list of BSS entries maintained by the adapter. This command can only be sent on the station port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

Set property parameters

No additional parameters. The data in the header is sufficient.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_MULTICAST_LIST

Article • 03/14/2023

OID_WDI_SET_MULTICAST_LIST specifies the multicast address list for a given port. This command can be set at any time.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

The IHV component should only fail the command if the list size exceeds the limit specified in **WDI_TLV_INTERFACE_ATTRIBUTES**.

After the host enables multicast packet filtering on the port using OID_WDI_SET_RECEIVE_PACKET_FILTER, the device must indicate received multicast frames with a destination address matching an address in the port's multicast list to the host. The device must clear the multicast list as part of processing of OID_WDI_TASK_DOT11_RESET. When the command is sent with no multicast list specified, the driver must clear its multicast list. In this case, no packets should be indicated up unless OID_WDI_SET_RECEIVE_PACKET_FILTER has the WDI_PACKET_FILTER_ALL_MULTICAST bit set.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_MULTICAST_LIST		X	List of multicast MAC addresses. The list must not be empty.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_NEIGHBOR_REPORT_ENTRIES

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_NEIGHBOR_REPORT_ENTRIES sends the list of neighbor reports received from the AP to the LE. This is sent as soon as the UE receives the neighbor report from the currently connected AP.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_NEIGHBOR_REPORT_ENTRY	X		The list of neighbor reports.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_NETWORK_LIST_OFFLOAD

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_NETWORK_LIST_OFFLOAD sets a list of preferred SSIDs for the firmware to scan for APs.

Scope	Set serialized with task	Normal execution time (seconds)
Primary port	Yes	1

There are two types of Network List Offload (NLO). One type is offload to NICs on Always On Always Connected (AOAC) systems. The other is Instant Connect NLO which, in Windows 8 and Windows 8.1, was only used for non-AOAC systems to quickly reconnect Wi-Fi at resume from hibernation. For Instant Connect, the list is sent down before the system goes into hibernation. Going forward, Instant Connect is used for resume from hibernation on AOAC systems that support it.

Instant Connect

WDI handles Instant Connect NLO and uses a combination of targeted scans to fulfill the request from the OS. IHV drivers do not need to handle this Instant Connect OS request.

When the OS resumes from hibernation, the OS sends an Instant Connect NLO. WDI makes a union of all channel hints for a targeted scan OID. IHV drivers should support such a targeted scan as defined in OID_WDI_TASK_SCAN. The following section applies to Network List Offload to capable NICs on AOAC systems.

Network List Offload

The OS does not request periodic background scans when in CS. A NLO scan is the preferred method in CS because the screen is off when users do not need to see all visible APs. SSIDs that users have auto-connect profiles set to auto-connect are the only useful APs. The list of SSIDs to offload from the OS has a preferred authentication and cipher pair, and up to four channel hints. When the list has a least one SSID, the firmware should start to do a NLO scan autonomously, following the schedule of fast scan and slow scan phases. The WDI compliant driver translates the operating system request to a firmware request. The firmware is expected to do a NLO scan according the schedule for the APs. The APs should support the preferred authentication and cipher pair associated with the SSIDs.

The request to the firmware has a list of channel hints for all offload SSIDs. The WDI compliant driver combines them for the firmware. For example, if SSID1[auth1, cipher1] has channel hints of 1 and 6, and SSID2[auth2, cipher2] has channel hints of 6 and 11, the request to the firmware is a list of SSIDs { SSID1[auth1, cipher1], SSID2[auth2, cipher2] } and list of channels to scan { 1, 6, 11 }.

In each scan period, the firmware scans for SSIDs that match the criteria on the list of channels, but not necessary constrained on the list of channels. The discovered AP information should be cached for the host to retrieve. The firmware indicates NLO discovery when at least one BSSID matches the SSID, algorithm, and cipher, but the channel match is not required.

Each OID_WDI_SET_NETWORK_LIST_OFFLOAD that the UE sends to the LE represents a fresh NLO scan request. Any previous such requests or states are renewed. LE scans for NLO and only indicates once for a found AP per request. The UE replumbs (12 times; this is subject to change) NLO at Dx transitions if a found AP is not connected successfully (due to reasons such as: an AP is found but devices move around, the AP signal fades, and the connection fails; or prolong EAP authentication fails partway through). The LE and firmware should delay the NLO scan schedule based on the delay configuration in **WDI_TLV_NETWORK_LIST_OFFLOAD_CONFIG**. This is a number that the UE uses to conform to the schedule of the operating system's original NLO command.

The default scan type for NLO is WDI_SCAN_TYPE_AUTO. When actively scanning a channel, the firmware should use the wildcard SSID. Visible APs should be compared with SSIDs on the offload list to decide a match. This is to reduce privacy exposure.

Indicating NLO discovery has two cases.

1. When the NIC is in D2, it must do the following steps.

    - Trigger the wake interrupt and wait for set power to D0 before continuing to the following steps.
    - Indicate that the firmware woke the stack with the reason of NLO discovery.
    - Return D0 command.

- Indicate NLO discovery with all of the found AP information.

2. When the NIC is in D0, it must do the following step.

   - Indicate NLO discovery with all of the found AP information.

Set property parameters

OID_WDI_SET_P2P_LISTEN_STATE

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_P2P_LISTEN_STATE sets the Wi-Fi Direct listen state on the port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

There are different levels of listen state, and the port is expected to adhere to concurrency requirements across ports.

This property is only applicable to virtualized Wi-Fi Direct Adapter Port interfaces.

When the listen state is active, the port is expected to park the radio on a social channel for a certain period of time.

If the adapter has a virtualized port operating on a non-social channel, the port may become discoverable on that channel. If this behavior is used, the port must be very highly available to allow other adapters to quickly discover it when in the scan phase of Wi-Fi Direct discovery. This is provided as a trade-off to avoid channel hopping in low latency scenarios.

Note This property specifies a radio time slice requirement to the port, which may cause conflicts with other properties or tasks issued to the port.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_LISTEN_STATE			Desired listen state.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CHANNEL_NUMBER		X	The host’s desired listen channel when enabling the Wi-Fi Direct listen state. If this option is not specified, the port may select a listen channel on its own.
WDI_TLV_P2P_LISTEN_DURATION			Cycle duration and listen time.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_P2P_START_BACKGROUND_DISCOVERY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_P2P_START_BACKGROUND_DISCOVERY instructs the adapter to periodically perform Wi-Fi Direct discovery in the background

Scope	Set serialized with task	Normal execution time (seconds)	Affects data throughput/latency
Port	No	1	Yes

The adapter is required to scan the specified channels at regular intervals and be able to find a device that becomes discoverable within the device visibility timeout (typically 5 minutes). The behavior is similar to the regular Wi-Fi Direct Discovery scan (as defined in OID_WDI_TASK_P2P_DISCOVER), but it is not time-bound, and the adapter may schedule the scans at some later point in time. The adapter must perform at least one scan within each device visibility timeout. If the device visibility timeout is 0, the adapter should continue to scan regularly using its own cycle time. If a DISCOVER or SCAN task request is made during this time, the adapter should suspend the background discovery for the duration of the task and continue when the task is finished. Upon completing a background scan, the device should send the NDIS_STATUS_WDI_INDICATION_P2P_DISCOVERY_COMPLETE indication (with transaction ID equal to 0) to let the operating system know that it has completed a scan. The adapter must send this indication every time it completes a background scan.

If the channel list is provided, the adapter should only scan on the specified channels. Otherwise, it should scan all channels. If the firmware happened to discover a device outside of the specified channels, it should still send the information to the operating system.

When Listen Duration and channels (**WDI_TLV_P2P_DISCOVERY_CHANNEL_SETTINGS**) are specified, they refer to the listen times for the remote devices. Based on all the values of Listen Duration and channels, the adapter needs to come up with a schedule to scan the requested channels in the most efficient manner. The operating system may also specify multiple instances of Listen Duration and channels. In this case, the adapter should first come up with the scan schedule for those entries which have non-zero values of Listen Duration and Channel list. Then, the adapter should use default values in the following cases:

1. If the Listen duration is 0, the adapter should use the default scan times for the specified channels.
2. If the channel list is empty, the adapter should scan all of the channels in that band using the listen and cycle times specified for that band. The scan times would not apply to any channels that have separate listen durations specified by the operating system.

When the NIC is in D0, the adapter indicates the responses to the probe requests for the specific service name(s) as NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST notifications to the operating system. WDI caches the response information for the OS for the higher layer services, and notifies them as necessary.

When the NIC is in D2, it suspends background discovery until it goes back to D0.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_BACKGROUND_DISCOVER_MODE			Wi-Fi Direct Background Discover Mode parameters.
WDI_TLV_P2P_DISCOVERY_CHANNEL_SETTINGS	X	X	List of recommended channels to scan.
WDI_TLV_P2P_DEVICE_FILTER_LIST		X	List of Wi-Fi Direct devices and Group Owners to search for during Wi-Fi Direct device discover.
WDI_TLV_P2P_SERVICE_NAME_HASH	X	X	List of Service Hash names to be queried. This is required if WDI_P2P_SERVICE_DISCOVERY_TYPE_SERVICE_NAME_ONLY is specified.
WDI_TLV_VENDOR_SPECIFIC_IE		X	One or more IEs that must be included in the probe requests sent by the port.

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_SET_POWER_STATE

Article • 03/14/2023

OID_WDI_SET_POWER_STATE sets the power state of the device.

Scope	Set serialized with task	Normal execution time (seconds)
Adapter	Yes	10

A NIC comes up in D0 (device fully powered) when the system boots or when the NIC is plugged in to the system. When the condition is right (on AOAC platforms, this is when NIC Active reference is 0 on the NIC), the operating system prepares and puts the NIC in D0. When users are not present, the host goes to low power state to save power. The host may set the NIC into a lower power state where the NIC can keep connections autonomously for the host. The NIC wakes up the host for external events that the host expresses interest in.

OID_WDI_SET_POWER_STATE sets the device into D0, D1, D2, and D3. The D states are device class and platform specific. A Wi-Fi NIC usually supports only a subset of the states. For example, for Wi-Fi devices on SD bus, the supported set consists of D0, D2, and D3. The meaning of D2 and D3 are device-specific as well. For a Wi-Fi NIC on SDIO bus, it is defined to be able to wake from D2, but in D3, the NIC is halted.

A PCIe bus NIC supports D0 and D3, where D3 can be D3Hot or D3Cold. On the host software stack, there is only D3. D3hot or D3Cold depends on the host scenarios and underlying platform support. For example, in connected standby scenarios, the host offloads wake events to the NIC and sets the NIC in D3, which is D3hot with platform support to keep the NIC powered so that the NIC can watch for external events for the host. In the hibernation scenario, the host sets the NIC in D3 and the platform turns off the power to the NIC so the NIC does not use any power.

For an AOAC system that supports hibernation, the following is a summary of important system power states. On an AOAC system, a system sleep state is a connected standby state. This is the state where NICs are set to low power (D2 for SDBus NICs, D3 for PCIe NICs) and armed to wake. If the driver is suspended to the hard drive, it is the driver’s responsibility to resume firmware states as the driver does not go through reinitialization again (for example, DriverEntry is not called).

	Sleep	Hibernation	Hybrid shutdown	Full shutdown

	Sleep	**Hibernation**	**Hybrid shutdown**	**Full shutdown**
Request by	Power button (default)	shutdown /h	shutdown /s /hybrid	shutdown /s
UI	**Start** > **Power** > **Sleep**	--	**Start** > **Power** > **Shutdown**	--
System state	Connected standby	Hibernation	Hybrid shutdown	Power off
Driver state	Alive - armed to wake	Suspend to hard drive	Suspend to hard drive	Power off

For an AOAC system where hibernation is not required or supported, here is the summary of driver power states.

	Sleep	**Full shutdown**
Request by	Power button (default)	shutdown /s
UI	**Start** > **Power** > **Sleep**	**Start** > **Power** > **Shutdown**
System state	Connected standby	Power off
Driver state	Alive - armed to wake	Power off

Set power commands cannot fail. The firmware should never fail such commands. The Microsoft component ensures that there are no outstanding tasks or commands when it sends any set power command. While the set power command is outstanding, the Microsoft component also guarantees that no other commands or tasks are sent to the IHV component.

Power state	**Description**
D0 (fully powered)	The NIC is fully powered and ready to receive commands. The host never requests changes between low power states. For example, if the host wants to set the NIC power state from D2 to D3, it first sets the power state to D0, and then to D3.
D2 and armed for wake (SDBus NICs)	In D2, the host never sends requests to the firmware except the Set D0 command. See later sections in this topic for relevant flow charts.

Power state	Description
D3: power off (SDBus NICs), armed for wake (PCIe NICs)	For SDBus NICs, this state is powered off. For PCIe bus NICs, the operating system may arm NICs for wakes (D3Hot) or may turn off the power (D3Cold). Note that from the driver stack perspective, there is only D3 state. Multiple components are involved to enable the D3Hot state, including the ACPI table and the processing of NDIS system power IRPs that come from the operating system depending on end-user actions or inactions, such as hibernation, Connection Standby, and hybrid shutdown.
Dx for non-default ports	Dx is either D2 or D3. When the NIC is put into Dx all non-default ports are reset, which means all non-default ports are disconnected in Dx.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_POWER_STATE			The power state. This applies to the primary port.
WDI_TLV_ENABLE_WAKE_EVENTS		X	This field may only appear when the NIC is being put into low power and is armed to wake on any of the specified events (such as D2 on SD IO).
WDI_TLV_SET_POWER_DX_REASON		X	The set power reason.

Set property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ADAPTER_RESUME_REQUIRED		X	If the value is true, it signals to the OS that the firmware needs assistance in resuming its context. This should only occur when the driver is suspended to storage. The IHV component must reset the software state because the operating system issues a series of Wi-Fi commands to bring the firmware context and IHV component context up to date.

Enable wake events

A NIC specifies the set of events that it can detect to wake the stack. The operating system plumbs down a subset or full set of the events to the NIC with the low power command. Some wake event parameters are set much earlier than the Dx command. Others are set right before the Dx command to the firmware. All events only become enabled with the Dx command.

In this interface, the event that is set to enabled is plumbed down in the optional WDI_TLV_ENABLE_WAKE_EVENTS TLV as part of the OID_WDI_SET_POWER command for device power state Dx. The TLV is absent if the operating system does not want to arm the NIC to wake.

When the firmware receives a Dx command with WDI_TLV_ENABLE_WAKE_EVENTS, it may detect a wake event before it completes the Dx command. It should buffer the event, finish processing the command, and then assert the wake interrupt.

Each and every wake by the Wi-Fi NIC should be followed by a wake reason for why the NIC wakes the stack. A NIC wakes the stack by asserting the wake interrupt line, which is typically serviced by the bus or ACPI methods. The methods wake the CPU and required components to handle the wake event, and complete the Wi-Fi Wait Wake IRP for the stack. Subsequently, the operating system issues a D0 request to the driver and firmware. This request is a power OID to the driver that sends a D0 command to the firmware. The firmware holds the indication of the wake reason until it receives and completes the D0 command.

Note If the NIC receives the D0 command for some other reason (for example, the NIC does not wake the host), the NIC should not indicate a wake reason.

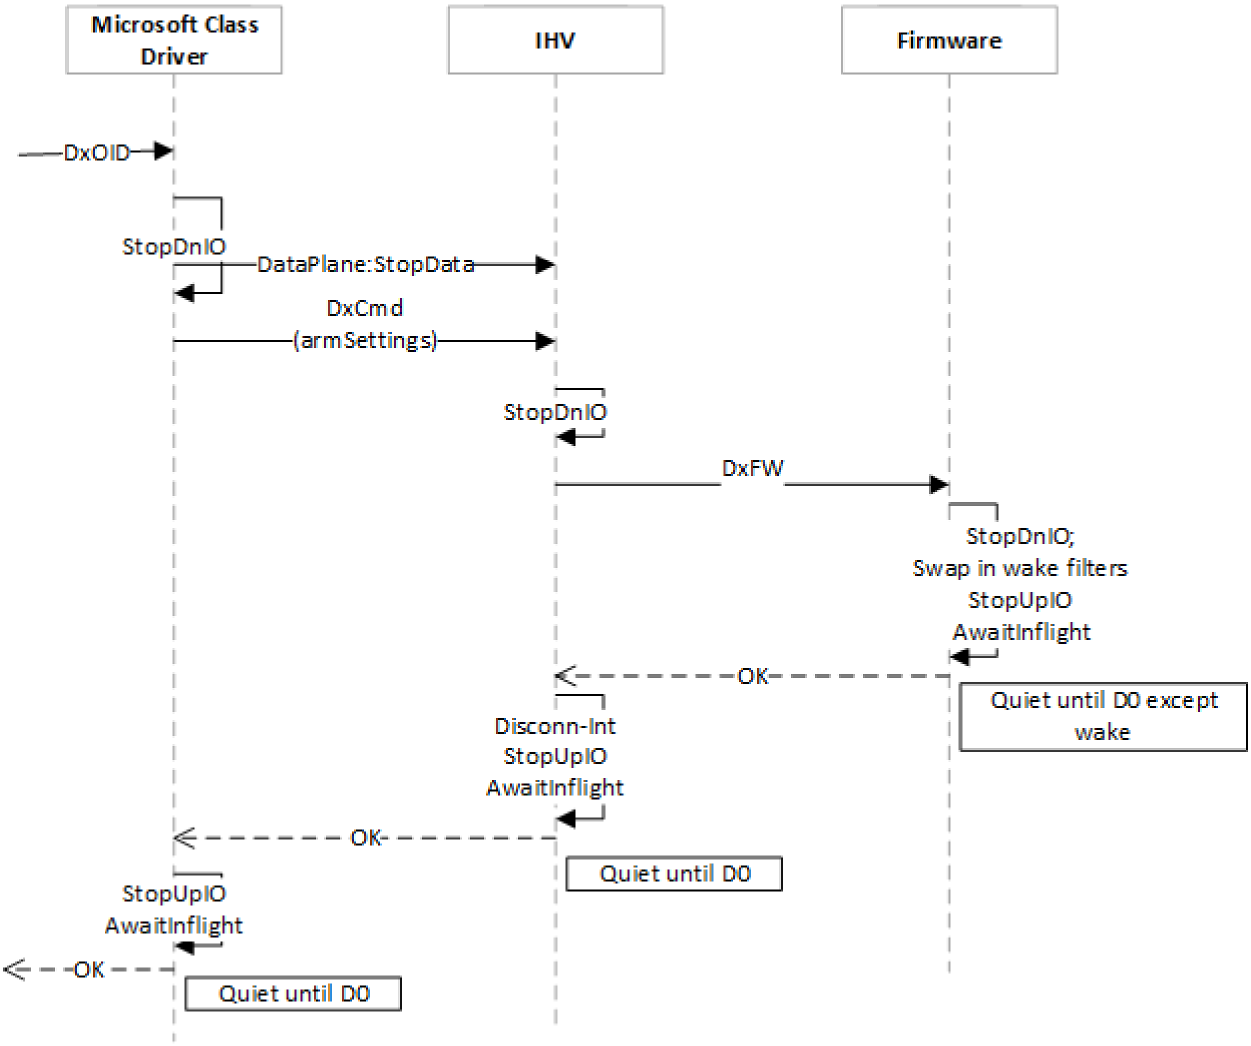
No enabled wake events

If there is no WDI_TLV_ENABLE_WAKE_EVENTS present, the operating system does not need the NICs to run at low power. The NICs may be completely powered off. If suspended to a hard drive, the NICs drivers are expected to resume firmware context at resume.

Power state interaction and transition examples

The following diagrams show interactions and sequences of transitions between D0 and Dx (D2 or D3) for the NIC. In this context, the "Miniport" represents the host or WDI compliant driver.

D0 to Dx (armed to wake)

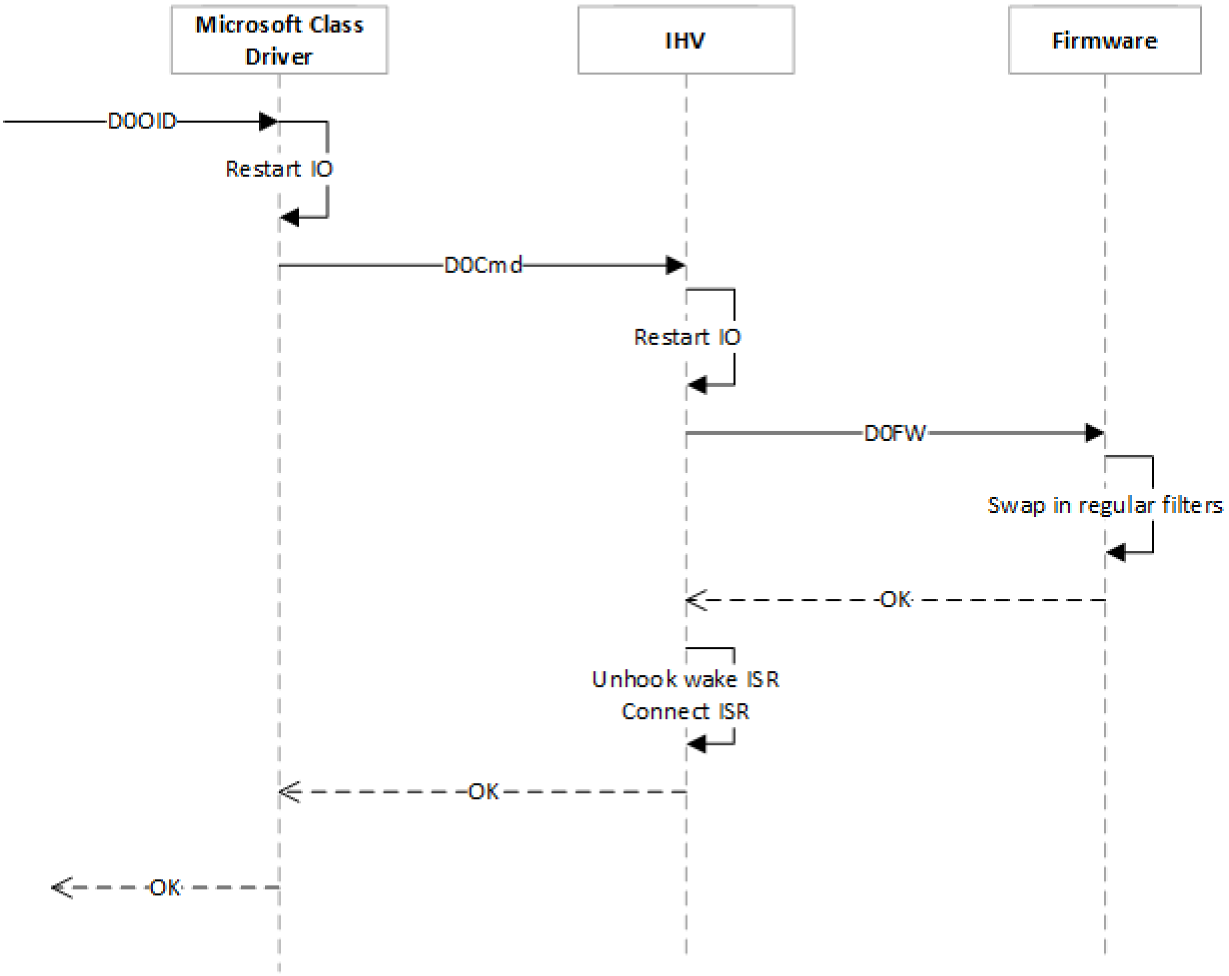


- Stop [DnIO|UpIO]: DnIO are messages (controls and data) to lower layer. UpIO are messages to upper layer.
  - Reject new requests from above layer (fail fast).
  - Stop initiating IO from this layer (except this Dx command).
  - Allow lower layer to inject TXs needed to go into Dx.
  - Flush queues.

- AwaitInflight: Waiting for IO calls to return, including DMA in progress. Flush queues.

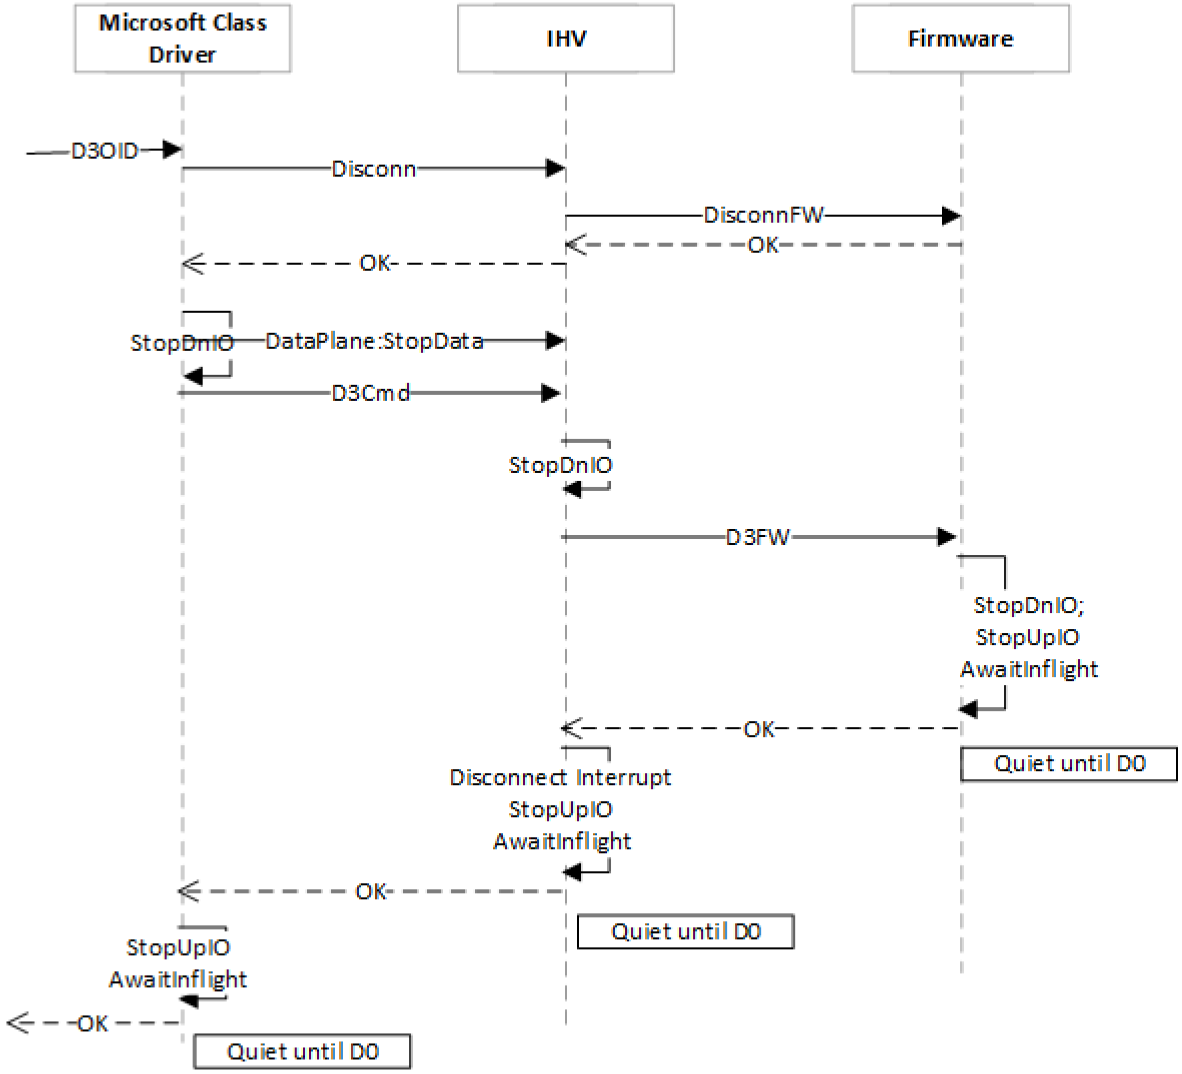
- Dx is any non-D0 state. For SDBus Wi-Fi, this is D2. For PCIe bus, this is D3Hot. Firmware shall not lose power.

Dx (armed to wake) to D0 transition



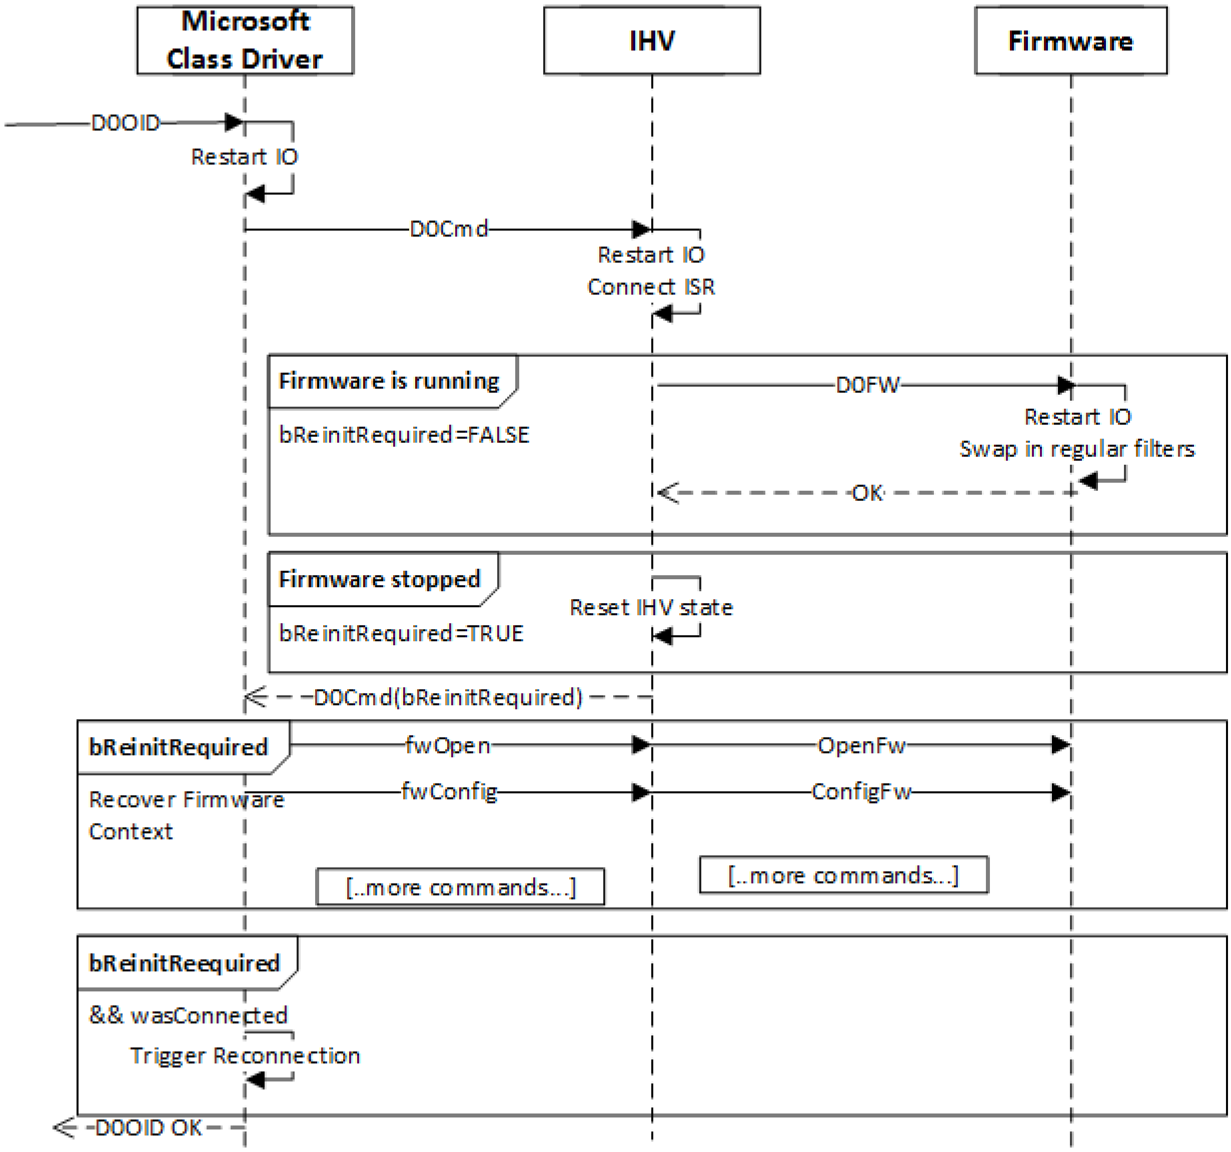
- If the NIC is armed to wake, it can't be D3Cold. Firmware must continue running in Dx.

D0 to D3 (not armed to wake) transition



- Stop [DnIO|UpIO]: DnIO are messages (controls and data) to lower layer. UpIO are messages to upper layer.
  - Reject new requests from above layer (fail fast).
  - Stop initiating IO from this layer (except this Dx command).
  - Allow lower layer to inject TXs needed to go into Dx.
  - Flush queues.
- AwaitInflight: Waiting for IO calls to return, including DMA in progress. Flush queues.
- D3 without PmParameters. The NIC may (D3Cold) or may not be powered off (for example, a shared power rail with a D0 device).

Dx (not armed to wake) to D0 transition



- D2 notArmToWake: Kept power, no reinitialization required.
- D3 notArmtoWake: Might be Hot or Cold. Cold requires that context be restored.

OID_WDI_SET_SAE_AUTH_PARAMS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_SET_SAE_AUTH_PARAMS is sent by WDI in response to an NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED indication from the driver. It contains the parameters required to send the Simultaneous Authentication of Equals (SAE) Commit or Confirm request, or an error message indicating a failure to perform SAE with the BSSID.

This command is sent as a Direct OID request to the driver.

For more information about SAE authentication, see WPA3 SAE authentication.

Command parameters

TLV	**Type**	**Multiple TLV instances allowed**	**Optional**	**Description**
WDI_TLV_BSSID	**WDI_MAC_ADDRESS**			The BSSID of the AP.
WDI_TLV_SAE_REQUEST_TYPE	**WDI_SAE_REQUEST_TYPE**			The type of SAE request frame to send to the BSSID.
WDI_TLV_SAE_COMMIT_REQUEST	WDI_SAE_COMMIT_REQUEST		X	The SAE Commit request parameters.
WDI_TLV_SAE_CONFIRM_REQUEST	WDI_SAE_CONFIRM_REQUEST		X	The SAE Confirm request parameters.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SAE_STATUS	**WDI_SAE_STATUS**		X	SAE authentication failure error status.

Minimum supported client: Windows 10, version 1903

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

OID_WDI_SET_TCP_OFFLOAD_PARAMETERS

Article • 03/14/2023

OID_WDI_SET_TCP_OFFLOAD_PARAMETERS is sent down to the device from the OS to set the TCP offload parameters.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Yes	1

This command is sent in some cases such as when there is a need to turn off the offloads due to a performance issue.

The lower edge driver (LE) must use the contents of **WDI_TLV_TCP_SET_OFFLOAD_PARAMETERS** to update the currently reported TCP offload capabilities. After the update, the LE must report the current task offload capabilities with NDIS_STATUS_WDI_INDICATION_TASK_OFFLOAD_CURRENT_CONFIG. This status indication ensures that all of the overlying protocol drivers are updated with the new capabilities information.

Set property parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_TCP_SET_OFFLOAD_PARAMETERS			The TCP offload parameters to be set.

Set property results

No additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10

NDIS_STATUS_WDI_INDICATION_CIPHER_KEY_UPDATED

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers send this indication to indicate that the cipher key(s) have been updated.

This indication is sent only while the driver has not offload the RSN GTK rekey (via the WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY filed in the OID_WDI_SET_ADD_PM_PROTOCOL_OFFLOAD command). If the driver is currently in the offload state for the Rsn GTK Rekey, then it should not indicate via this method and should allow the updated key information to be queried via the OID_WDI_GET_PM_PROTOCOL_OFFLOAD command when it comes out of the offload state.

For example, the driver would send this notification if it or the firmware receives a new GTK/iGTK in the WNM-Sleep mode response.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PM_PROTOCOL_RSN_OFFLOAD_KEYS			The currently configured Rsn Eapol key information.

Requirements

Minimum supported client: Windows 10, version 1803

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

The NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT status indication is used by an IHV miniport driver to pass on unsolicited information about a device to a user mode client.

Device service indications must be sent by the miniport driver only when in the *D0* power state, and it must not cause the device to wake from *Dx*. WDI will drop this indication without forwarding it up the stack if it receives it when in *Dx*.

This indication is currently handled only on the default port (station).

The miniport driver should send a separate notification for every device service GUID and opcode pair whenever necessary.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DEVICE_SERVICE_PARAMS_DATA_BLOB		X	The information received from the IHV miniport driver.
WDI_TLV_DEVICE_SERVICE_PARAMS_GUID			The GUID that identifies the device service to which this indication belongs (as defined by the IHV/OEM).

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DEVICE_SERVICE_PARAMS_OPCODE			The opcode specific to the device service.

Requirements

Minimum supported client: Windows 10, version 1809

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_DISASSOCIATION

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_DISASSOCIATION to indicate that a port disconnected from the network.

Object
Port

The disconnect may be triggered by a command from the operating system or triggered from the network. Network triggered disconnect may be explicit from received disassociation or deauthentication packets, or may be implicit when the port cannot detect the presence of the peer it is connected to.

Before the disassociation indication is sent, the port must clear the state associated with this peer. This includes any keys and 802.1x port authorization information associated with this peer. The port must not trigger a roam on its own.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DISASSOCIATION_INDICATION_PARAMETERS			The disassociation indication parameters.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DISCONNECT_DEAUTH_FRAME		X	The deauthentication frame that was received. This does not include the 802.11 MAC header.
WDI_TLV_DISCONNECT_DISASSOCIATION_FRAME		X	The disassociation frame that was received. This does not include the 802.11 MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_FT_ASSOC_PARAMS_NEEDED

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_FT_ASSOC_PARAMS_NEEDED to request parameters for 802.11r roaming.

Object
Port

During OID_WDI_TASK_ROAM, WDI provides the parameters to send the 802.11 Authentication Request (PmkR0Name, R0KH-ID, SNonce, MDIE). Upon receiving the Authentication response, the LE requests additional needed parameters for the reassociation request, such as PMKR1Name and R1KH-ID. The LE also sends the parameters received in the Authentication Response (ANonce, SNonce, and R1KHID).

For a connection where Initial Mobility Domain is successfully done, the LE should only perform 11r roams (Fast roams). The LE can use the candidate list provided by the operating system, or use their own for the roams. If the LE uses its own candidate list, it must use the parameters (MDE, FTE, and PMKR0Name) provided in any one of the candidates suggested by the operating system to do a 11r roam. 11r is disabled whenever the connection is in FIPS mode. 11r fast roaming is currently only supported for FT over 1x authentication type.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			The BSSID of the AP.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_FT_AUTH_REQUEST			The authentication request byte blob.
WDI_TLV_FT_AUTH_RESPONSE			The authentication response byte blob.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_LINK_STATE_CHANGE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_LINK_STATE_CHANGE to indicate any of the following situations:

- The link speed changed.
- The link quality changed by more than a threshold value. The threshold is 1 if the connection quality hint is set to WDI_CONNECTION_QUALITY_LOW_LATENCY (defined in WDI_CONNECTION_QUALITY_HINT). Otherwise, the threshold is 5.

Object
Port

This information from this indication is used by the host to keep track of metadata about the current link, and it may be propagated to the user.

In Station and P2P Client cases, the Peer MAC Address is set to the BSSID of the connected network. In AP/P2P GO cases, the Peer MAC Address is set to the MAC address of a given connected device.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_LINK_STATE_CHANGE_PARAMETERS			The link state change parameters.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_NLO_DISCOVERY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_NLO_DISCOVERY to indicate Network List Offload (NLO) discovery.

Object
Port

The firmware detects APs for SSIDs pushed down in NLO. NLO is used in non-AOAC systems for fast connection when resuming from system sleep. It is also used in AOAC systems to scan APs for SSIDs that are pushed to the firmware.

The OS does not request periodic background scans when in CS. NLO scan is the preferred method in CS because the screen is off when users don't need to see all visible APs but those for SSIDs that users have auto-connect profiles to auto connect to. The list of SSIDs to offload from the OS has a preferred authentication and cipher pair and up to 4 channel hints. When the list has at least one SSID, the firmware should start an NLO scan autonomously following the schedule of fast scan and slow scan phases. The class driver translates the OS request to a firmware request. The firmware is expected to do NLO scan according the schedule for the APs that support the preferred authentication and cipher pair associated with the SSIDs.

In each scan period, the firmware scans for SSIDs that match the criteria on the list of channels but not necessary constrained on the list of channels. The discovered AP information should be cached for indication.

When any matches are found, the firmware indicates NLO discovery and caches the list of discovered AP information for the host to retrieve.

The indication of NLO discovery happens in the following two cases.

- When the NIC is in Dx:

    1. Trigger the wake interrupt and wait for set power to D0 to continue the following steps.
    2. Indicate NLO discovery.
    3. Indicate that the firmware woke the stack with the reason of NLO discovery.

- When the NIC is in D0:
    - Indicate NLO discovery.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSS_ENTRY	X		A list of BSSIDs. The list must at least contain the entry that triggered this discovery status.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

NDIS_STATUS_WDI_INDICATION_P2P_ACTION_FRAME_RECEIVED

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_P2P_ACTION_FRAME_RECEIVED to indicate that a Wi-Fi Direct Action Frame has been received.

Object
Port

The host may issue an OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME for this request.

The port must indicate these packets in any of the following situations:

- The port is in listen state.
- The port has a GO in operational state.
- The port is dwelling on a remote listen channel when an OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME or OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME has been recently issued.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_INCOMING_FRAME_INFORMATION			The incoming Wi-Fi Direct Action Frame information. This information is forwarded back to the port when the host issues OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_P2P_GROUP_OPERATING_CHANNEL

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_P2P_GROUP_OPERATING_CHANNEL to indicate which operating channel a given Wi-Fi Direct port is operating on.

For a Wi-Fi Direct Client port, this must be indicated during the connect (before the connect completion).

For a Wi-Fi Direct GO port, this must be indicated during OID_WDI_TASK_START_AP (before the OID completion).

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CHANNEL_NUMBER			The operating channel the given Wi-Fi Direct port is operating on.
WDI_TLV_P2P_CHANNEL_INDICATE_REASON			The reason for sending the indication.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_P2P_OPERATING_CHANNEL_ATTRIBUTES

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_P2P_OPERATING_CHANNEL_ATTRIBUTES to indicate the preferred operating channel to start a GO, the preferred listen channel if asked to enter listen state, and the full set of supported channels at any point of time. The indication is sent once when adapter initializes, and then sent each time one of these parameters changes due to events such as roaming or connecting or disconnecting from an access point.

Object
Port

The operating channel and channel list values are local settings and do not account for the actual channel negotiation during GO negotiation/invitation. The driver is still expected to negotiate the channel when GO negotiation/invitation is performed.

It is expected that the listen channel reported by the driver is honored if listen state is turned on. It is expected that this indication is fired if the host configured a listen channel that is different from the preferred listen channel reported earlier via this indication.

Payload data

Type	Multiple TLV instances allowed	Optional	Description

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CHANNEL_NUMBER			The Wi-Fi Direct Operating channel attribute.
WDI_TLV_P2P_CHANNEL_LIST_ATTRIBUTE			The full set of channels supported by the local adapter.
WDI_TLV_P2P_LISTEN_CHANNEL			The Wi-Fi Direct Listen channel attribute.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers send the **NDIS_STATUS_WDI_INDICATION_REQUEST_FTM_COMPLETE** status indication to the host as a task completion indication for OID_WDI_TASK_REQUEST_FTM. This notification contains a list of Fine Timing Measurement (FTM) responses received from each requested target.

Payload data

Type	TLV	Multiple TLV instances allowed	Optional	Description
WDI_STATUS	A field in the header.		The general completion status of the event.	
WDI_TLV_FTM_RESPONSE	Multiple TLV<WDI_TLV_FTM_RESPONSE>	X		A list of FTM responses for each target.

Requirements

Minimum supported client: Windows 10, version 1903

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_ROAM_COMPLETE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_ROAM_COMPLETE to indicate the completion of OID_WDI_TASK_ROAM.

Object
Port

Payload data

This indication contains no additional data. The data in the header is sufficient.

Requirements

Minimum supported client	Windows 10

NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_DISASSOCIATION to indicate that the host should try to find a better peer to connect to. This notification is used when the link quality with the currently connected peer falls below a certain threshold. On sending this notification, the host may trigger a roam scan and/or a roam operation. The Microsoft component does not perform a disconnect before it starts the roam operation.

Object
Port

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ROAMING_NEEDED_PARAMETERS			The reason for the roam trigger. When a OID_WDI_TASK_ROAM is triggered, this reason is forwarded to it.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

The Wi-Fi adapter sends this indication to request parameters for Simultaneous Authentication of Equals (SAE) authentication.

When the miniport driver is requested to perform SAE authentication with a target BSSID, it needs to request information at various stages of authentication. Initially, it requests parameters for the Commit request frame, then the Confirm request frame if successful. If the driver encounters an irrecoverable timeout or error, it also indicates that to the OS.

This indication is sent during the SAE authentication process. For more information, see WPA3-SAE authentication.

Payload data

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID	**WDI_MAC_ADDRESS**			The BSS ID of the AP.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SAE_INDICATION_TYPE	**WDI_SAE_INDICATION_TYPE**			The type of information needed to continue SAE authentication with the BSSID, or notification that authentication cannot continue.
WDI_TLV_SAE_COMMIT_RESPONSE	TLV<LIST<UINT8>>		X	The SAE Commit Response frame.
WDI_TLV_SAE_CONFIRM_RESPONSE	TLV<LIST<UINT8>>		X	The SAE Confirm Response frame.
WDI_TLV_SAE_STATUS	**WDI_SAE_STATUS**		X	The SAE authentication failure error status.

Requirements

Minimum supported client: Windows 10, version 1903

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_TASK_OFFLOAD_CURRENT_CONFIG

Article • 03/14/2023

Miniport drivers use NDIS_STATUS_WDI_INDICATION_TASK_OFFLOAD_CURRENT_CONFIG to indicate when there is a change in the TCP offload capabilities of the hardware.

Object
Port

When there is a change in the TCP offload capabilities of the hardware, the LE sends this unsolicited indication to the UE, with the new TCP checksum/LSO capabilities. Use the values **NDIS_OFFLOAD_SET_OFF** and **NDIS_OFFLOAD_SET_ON** for members in WDI_TLV_TCP_OFFLOAD_CAPABILITIES for indicating changes in offload capabilities. When the UE sends down a OID_WDI_SET_TCP_OFFLOAD_PARAMETERS, the LE should update the offload capabilities and then send this indication so that the OS is updated with the latest offload capabilities information.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_TCP_OFFLOAD_CAPABILITIES		X	The TCP/IP checksum and Large Send Offload capabilities.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_TKIP_MIC_FAILURE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

Miniport drivers use NDIS_STATUS_WDI_INDICATION_TKIP_MIC_FAILURE to indicate when a received packet that was successfully decrypted by the TKIP cipher algorithm fails the message integrity code (MIC) verification.

Object
Port

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_TKIP_MIC_FAILURE_INFO			The TKIP MIC failure information.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

NDIS_STATUS_WDI_INDICATION_WAKE_REASON

Article • 03/14/2023

Miniport drivers use NDIS_STATUS_WDI_INDICATION_WAKE_REASON to indicate the reason for a wake when the NIC wakes the host. The wake reason is used for debugging purposes and has no functional effect.

Object
Port

When the host goes to low power state, it offloads a few functions to the NIC and arms the NIC for wake. When a wake event occurs, the NIC asserts the wake interrupt line to wake the host. The host then brings the NIC into D0 (running power state). The NIC must indicate the wake reason once it enters D0.

If the wake reason is a wake packet, the NIC should also include the wake packet and the wake pattern ID that matches the packet. The packet is encapsulated as WDI_TLV_INDICATION_WAKE_PACKET. The wake reason should also include WDI_TLV_INDICATION_WAKE_PACKET_PATTERN_ID to specify the pattern ID which matches the packet.

Payload data

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_INDICATION_WAKE_REASON			The wake reason.
WDI_TLV_INDICATION_WAKE_PACKET		X	The wake packet.
WDI_TLV_INDICATION_WAKE_PACKET_PATTERN_ID		X	The ID of the pattern that matches the wake packet. The ID is obtained from the Add command of the pattern.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

WDI_BAND_ID

Article • 03/03/2023

The WDI_BAND_ID data type is a UINT32 value that defines a band ID.

```C++
typedef UINT32 WDI_BAND_ID;
```

Remarks

Possible band ID values are as follows:

Name	Value	Description
WDI_BAND_ID_ANY	0xFFFFFFFF	All bands
WDI_BAND_ID_2400	1	2.4 GHz
WDI_BAND_ID_5000	2	5 GHz
WDI_BAND_ID_60000	3	60 GHz
WDI_BAND_ID_900	4	900 MHz
WDI_BAND_ID_CUSTOM_START	0x80000000	Specifies the start of the range that is used to define a band ID reported by an IHV.
WDI_BAND_ID_CUSTOM_END	0x81000000	Specifies the end of the range that is used to define a band ID reported by an IHV.

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_CHANNEL_NUMBER

Article • 03/03/2023

The WDI_CHANNEL_NUMBER data type is a UINT32 value that defines a channel number.

C++

```
typedef UINT32 WDI_CHANNEL_NUMBER;
```

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_EXTENDED_TID

Article • 03/03/2023

The WDI_EXTENDED_TID data type is a UINT8 value that defines a traffic identifier (TID).

```c++
typedef UINT8 WDI_EXTENDED_TID;
```

Remarks

Possible values are as follows:

Value	Description
0-15	802.11 TIDs
16 (WDI_EXT_TID_NON_QOS)	Non-QoS data
17-24	Reserved for use with IHV-injected frames. Frames with extended TID in the interval 17-24 are considered higher priority than those with a smaller extended TID in the same interval 17-24.
25-30	Unused values
31 (WDI_EXT_TID_UNKNOWN)	Unknown/unspecified

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

WDI_FRAME_ID

Article • 03/03/2023

The WDI_FRAME_ID data type is a UINT16 value that defines a frame ID. This is only an identifier. It does not convey information about the ordering of frames.

```c++
typedef UINT16 WDI_FRAME_ID;
```

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

WDI_PEER_ID

Article • 03/03/2023

The WDI_PEER_ID data type is a UINT16 value that defines a peer ID.

```c++
typedef UINT16 WDI_PEER_ID;
```

Remarks

If you want to specify any peer (wildcard), you can use the WDI_PEER_ANY (0xFFFF) value.

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

WDI_PORT_ID

Article • 03/03/2023

The WDI_PORT_ID data type is a UINT16 value that defines a port ID.

C++

```cpp
typedef UINT16 WDI_PORT_ID;
```

Remarks

If you want to specify any port (wildcard), you can use the WDI_PORT_ANY (0xFFFF) value.

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h

TAL_TXRX_HANDLE

Article • 12/15/2021

The TAL_TXRX_HANDLE data type is an NDIS_HANDLE value.

```c++
typedef NDIS_HANDLE TAL_TXRX_HANDLE, *PTAL_TXRX_HANDLE;
```

Requirements

Minimum supported client: Windows 10

Minimum supported server: Windows Server 2016

Header: Dot11wdi.h (include Ndis.h)

Features not carried over in WDI

Article • 03/14/2023

The following features are available in the previous Native WLAN driver model, but are not available in WDI.

- Soft AP
- IBSS
- Netmon

The following Soft AP required features are ported to Wi-Fi Direct.

- Added 802.11b.
- Moved all tethering requirements for Soft AP to Wi-Fi Direct.

WPA3-SAE authentication

Article • 12/15/2021

WPA3-SAE, also known as WPA3-Personal, is supported in Windows with WDI version 1.1.8 and later. Frame content generation and parsing for SAE (Secure Authentication of Equals) authentication is done within Windows, but the OS requires driver support for sending and receiving WPA3-SAE authentication frames.

WPA3-SAE capabilities

Miniport drivers indicate SAE support by doing the following:

1. Set SAE supported capability.
   The driver sets the **SAEAuthenticationSupported** capability in WDI_TLV_INTERFACE_ATTRIBUTES during the call to OID_WDI_GET_ADAPTER_CAPABILITIES.
2. Set MFP capability.
   The driver sets the **MFPCapable** capability in WDI_TLV_STATION_ATTRIBUTES during the call to OID_WDI_GET_ADAPTER_CAPABILITIES.
3. Add the **WDI_AUTH_ALGO_WPA3_SAE** auth method.
   The driver includes **WDI_AUTH_ALGO_WPA3_SAE** in the list of auth-cipher combinations returned in the call to OID_WDI_GET_ADAPTER_CAPABILITIES. This should be added in the following sections:

   - WDI_TLV_STATION_ATTRIBUTES : : WDI_TLV_UNICAST_ALGORITHM_LIST
   - WDI_TLV_STATION_ATTRIBUTES : : WDI_TLV_MULTICAST_DATA_ALGORITHM_LIST

WPA3-SAE authentication flow

Connection initiation

SAE connections are initiated with OID_WDI_TASK_CONNECT or OID_WDI_TASK_ROAM. WDI specifies **WDI_AUTH_ALGO_WPA3_SAE** as the auth method when the driver is required to do SAE authentication. If WDI provides the PMKID in the BSS list in the Connect/Roam task, then the driver skips SAE authentication and performs Open Authentication instead, followed by a reassociation request with the PMKID.

Initial request for SAE parameters

The driver first selects a BSS to which to connect or roam and, if WDI did not provide the PMKID for that BSS, the driver requests Commit parameters from WDI with NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED. In this initial indication, the driver sets the indication type to **WDI_SAE_INDICATION_TYPE_COMMIT_REQUEST_PARAMS_NEEDED**. In response, WDI sends OID_WDI_SET_SAE_AUTH_PARAMS to the driver with one of the following options.

- Send Commit request (**WDI_SAE_REQUEST_TYPE_COMMIT_REQUEST**)
- Fail SAE authentication (**WDI_SAE_REQUEST_TYPE_FAILURE**)

Upon receiving a Commit response

On receiving a Commit response, the driver sends NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED with the type set to **WDI_SAE_INDICATION_TYPE_COMMIT_RESPONSE**. In response, WDI sends OID_WDI_SET_SAE_AUTH_PARAMS with one of the following requests:

- Send Commit request (**WDI_SAE_REQUEST_TYPE_COMMIT_REQUEST**)
- Send Confirm request (**WDI_SAE_REQUEST_TYPE_CONFIRM_REQUEST**)

- Fail SAE authentication (**WDI_SAE_REQUEST_TYPE_FAILURE**)

Upon receiving a Confirm response

On receiving a Confirm response, the driver sends NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED with the type set to **WDI_SAE_INDICATION_TYPE_CONFIRM_RESPONSE**. WDI then sends OID_WDI_SET_SAE_AUTH_PARAMS with the SAE status field set to success or failure. If SAE authentication fails in the driver due to timeouts or other reasons, the driver sends an NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED indication with the type se to **WDI_SAE_INDICATION_TYPE_ERROR** and the failure reason specified in WDI_TLV_SAE_STATUS.

Timeouts and retransmissions

These are handled by the driver.

WPA3-SAE association

The device connects to an SAE network using one of the following options.

(Re)Association following SAE exchange

This is normally the first association attempt to an SAE network. The driver sets the SAE AKM in the RSN IE in the Association Request frame.

(Re)Association using PMKID

If WDI provided a PMKID for the BSS entry in the connect/roam task, then the driver does the following:

1. The driver performs an Open authentication followed by inclusion of the PMKID in the (Re)association request.
2. If the device does not receive a response from the AP within a short time, or if the AP returns an association error in the response, the driver skips SE authentication with this AP and either moves to another AP, or falls back to doing full SAE authentication with this AP.

SAE connection completes once the SAE authentication/association is complete. As before, the driver sends the following indications on conclusion of the connect or roam task:

- NDIS_STATUS_WDI_INDICATION_ASSOCIATION_RESULT
- NDIS_STATUS_WDI_INDICATION_CONNECT_COMPLETE

Error handling

Resending the SAE Commit request frame

If the driver needs to resend a Commit frame due to a timeout, it can either resend the original Scalar/Element values that were provided by WDI, or request a new set of Scalar/Element values from WDI with an NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED indication.

Resending the SAE Confirm response frame

If the driver needs to resend a Confirm frame due to a timeout, it should request a new set of **SendConfirm** and **Confirm** values from WDI with an NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED indication, setting the type to **WDI_SAE_INDICATION_TYPE_CONFIRM_REQUEST_RESEND_REQUEST**.

WDI doc change history

Article • 03/14/2023

Windows 10, version 2004

Documentation updated to WDI version 1.1.9.

Topic	Description
WDI message structure	Modified TLV structure and aggregate container to allow for variable-size KCK/KEK.
OID_WDI_TASK_REQUEST_FTM	**ScanTrigger** enum value added. Description updated for LE with BSS list cache.
WDI_AUTH_ALGORITHM	Added new WDI_AUTH_ALGORITHM **WDI_AUTH_ALGO_OWE**.
WDI_CIPHER_ALGORITHM	**WDI_CIPHER_ALGO_GCMP_256** new cipher added. **WDI_CIPHER_ALGO_BIP_GMAC_256** new cipher added.
WDI_TLV_CONFIGURED_CIPHER_KEY	Added entries for WDI_TLV_CIPHER_KEY_GCMP_256_KEY and WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY.
WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY	Newly added TLV type.
WDI_TLV_CIPHER_KEY_GCMP_256_KEY	Newly added TLV type.
WDI_TLV_CONNECT_PARAMETERS	Added reference for new TLV type WDI_TLV_OWE_DH_IE.
WDI_TLV_FTM_RESPONSE	**BandwidthUsed** field added. **PropegationProperty** field added. **RTT** field changed to signed integer.
WDI_TLV_KCK_CONTENT	Newly added TLV type.
WDI_TLV_KEK_CONTENT	Newly added TLV type.
WDI_TLV_OWE_DH_IE	Newly added TLV type.
WDI_TLV_PROTOCOL_OFFLOAD	Newly added TLV type.
WDI_TLV_REPLAY_COUNTER	Newly added TLV type.
WDI_TLV_STATION_CAPABILITIES	**Host-WPA3-FIPS** mode added.

Windows 10, version 1903

Documentation updated to WDI version 1.1.8.

Topic	Description
WDI_TLV_STATION_CAPABILITIES	Added support for the driver to indicate support for Fine Timing Measurement (FTM).
OID_WDI_TASK_REQUEST_FTM	Newly added task OID that enables WDI to request that the adapter initiate FTM procedures to obtain roundtrip time (RTT) and the Location Configuration Information (LCI) report from BSS targets.
WDI_TLV_FTM_REQUEST_TIMEOUT	Newly added TLV for FTM request.
WDI_TLV_FTM_TARGET_BSS_ENTRY	Newly added TLV for FTM request.

Topic	Description
WDI_TLV_REQUEST_LCI_REPORT	Newly added TLV for FTM request.
NDIS_STATUS_WDI_INDICATION_REQUEST_FTM_COMPLETE	Newly added status indication sent by the host as a task completion indication for OID_WDI_TASK_REQUEST_FTM. Contains a list of FTM responses from BSS targets.
WDI_TLV_FTM_RESPONSE	Newly added TLV for FTM response.
WDI_TLV_FTM_RESPONSE_STATUS	Newly added TLV for FTM response.
WDI_TLV_RETRY_AFTER	Newly added TLV for FTM response.
WDI_TLV_FTM_NUMBER_OF_MEASUREMENTS	Newly added TLV for FTM response.
WDI_TLV_RTT	Newly added TLV for FTM response.
WDI_TLV_RTT_ACCURACY	Newly added TLV for FTM response.
WDI_TLV_RTT_VARIANCE	Newly added TLV for FTM response.
WDI_TLV_LCI_REPORT_STATUS	Newly added TLV for FTM response.
WDI_TLV_LCI_REPORT_BODY	Newly added TLV for FTM response.
WDI_TLV_INTERFACE_CAPABILITIES	Added new capabilities for the driver to indicate support for Multiband Operation (MBO) and beacon report offloading.
WDI_ASSOC_STATUS	Added **WDI_ASSOC_STATUS_ASSOCIATION_DISALLOWED** status.
WPA3-SAE authentication	New overview of WPA3-SAE (Secure Authentication of Equals) authentication.
WDI_TLV_INTERFACE_CAPABILITIES	Added new capability for the driver to indicate support for SAE authentication.
WDI_AUTH_ALGORITHM	Added definition for **WDI_AUTH_ALGO_WPA3_SAE**.
NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED	Newly added status indication sent by the driver to request SAE authentication parameters from WDI.
WDI_TLV_SAE_INDICATION_TYPE	Newly added TLV for SAE authentication parameters requests.
WDI_TLV_SAE_COMMIT_RESPONSE	Newly added TLV for SAE authentication parameters requests.
WDI_TLV_SAE_CONFIRM_RESPONSE	Newly added TLV for SAE authentication parameters requests.
WDI_TLV_SAE_STATUS	Newly added TLV for SAE authentication parameters requests and for setting SAE authentication parameters.
OID_WDI_SET_SAE_AUTH_PARAMS	Newly added property OID that contains the parameters required to send the SAE Commit or Confirm request, or an error message indicating a failure to perform SAE with the BSSID.
WDI_TLV_SAE_REQUEST_TYPE	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_COMMIT_REQUEST	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_FINITE_CYCLIC_GROUP	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_SCALAR	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_ELEMENT	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_ANTI_CLOGGING_TOKEN	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_CONFIRM_REQUEST	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_SEND_CONFIRM	Newly added TLV for setting SAE authentication parameters.
WDI_TLV_SAE_CONFIRM	Newly added TLV for setting SAE authentication parameters.

Topic	Description
OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME	Added additional validation of P2P IEs on outgoing action frames.
OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME	Added additional validation of P2P IEs on outgoing action frames.

Windows 10, version 1809

Documentation updated to WDI version 1.1.7.

Topic	Description
WDI_PHY_TYPE	Added support for 802.11ax PHY.
WDI_CONNECTION_QUALITY_HINT	Changed the name of the **WDI_CONNECTION_QUALITY_HIGH_CHANNEL_AVAILABILITY** value to **WDI_CONNECTION_QUALITY_HIGH_THROUGHPUT**. No change to the description of this value.
NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT	Added support for unsolicited device service notifications.

Windows 10, version 1803

Documentation updated to WDI version 1.1.6.

Topic	Description
WDI_TLV_OS_POWER_MANAGEMENT_FEATURES	Added this TLV to OID_WDI_GET_ADAPTER_CAPABILITIES to indicate which OS power management (PM) features that the driver supports.
WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY	Updated this TLV to specify that drivers must now return GTK/iGTK key info, if configured, when queried in OID_WDI_GET_PM_PROTOCOL_OFFLOAD.
NDIS_STATUS_WDI_INDICATION_CIPHER_KEY_UPDATED	Added this indication for drivers to provide notifications of GTK/iGTK key updates when the keys are updated, while the driver is not in the Offload state.
MINIPORT_WDI_TX_SUSPECT_FRAME_LIST_ABORT	Updated *TxSuspectFrameListAbortHandle* to *TxSuspectFrameListAbort*.

Windows 10, version 1709

Documentation updated to WDI version 1.1.5.

Topic	Description
WDI_TLV_TCP_OFFLOAD_CAPABILITIES	Added new **WDI_TLV_OFFLOAD_SCOPE** parameter to indicate whether offloads specified apply to the STA port only or to all ports.
NDIS_STATUS_WDI_INDICATION_SEND_AP_ASSOCIATION_RESPONSE_COMPLETE	Changed the **WDI_TLV_PHY_TYPE_LIST** parameter to make it required.
User-initiated feedback with IHV trace logging	Added a new section describing how to add IHV logging to user-initiated feedback scenarios.

Windows 10, version 1607

Documentation updated to WDI version 1.0.21.

Topic	Description

Topic	Description
OID_WDI_TASK_P2P_DISCOVER	Added new task parameters: - WDI_TLV_P2P_ASP2_SERVICE_INFORMATION_DISCOVERY_ENTRY - WDI_TLV_P2P_INCLUDE_LISTEN_CHANNEL
OID_WDI_GET_ADAPTER_CAPABILITIES	Added new get property result: WDI_TLV_SUPPORTED_GUIDS
WDI_CIPHER_ALGORITHM	Added new value: WDI_CIPHER_ALGO_GCMP
WDI_PHY_TYPE	Added new value: WDI_PHY_TYPE_DMG
WDI_P2P_SERVICE_DISCOVERY_TYPE	Added new values: - WDI_P2P_SERVICE_DISCOVERY_TYPE_ASP2_SERVICE_NAME_ONLY - WDI_P2P_SERVICE_DISCOVERY_TYPE_ASP2_SERVICE_INFORMATION
WDI_TLV_P2P_ASP2_ADVERTISED_SERVICE_ENTRY WDI_TLV_P2P_ASP2_SERVICE_INFORMATION_DISCOVERY_ENTRY WDI_TLV_P2P_INCLUDE_LISTEN_CHANNEL WDI_TLV_P2P_INSTANCE_NAME WDI_TLV_P2P_INSTANCE_NAME_HASH WDI_TLV_P2P_SERVICE_TYPE WDI_TLV_P2P_SERVICE_TYPE_HASH WDI_TLV_SUPPORTED_GUIDS	Newly added TLVs.
WDI_TLV_P2P_ADVERTISED_SERVICES	Added contained TLV: WDI_TLV_P2P_ASP2_ADVERTISED_SERVICE_ENTRY
WDI_TLV_INTERFACE_CAPABILITIES	Added a new value that specifies if the device supports IP docking capability.
WDI_TLV_P2P_CAPABILITIES	Added a new value that specifies if ASP2 Service Names Discovery is supported. Added a new value that specifies if ASP2 Service Information Discovery is supported.

March 2016

Topic	Description
MINIPORT_WDI_TX_TARGET_DESC_DEINIT	Added note that the IHV miniport is not permitted to make any indication in the context of this call.
MINIPORT_WDI_TX_TARGET_DESC_INIT	Added note that the IHV miniport is not permitted to make any indication in the context of this call.

Windows 10, version 1511

Documentation updated to WDI version 1.0.10.

Topic	Description
OID_WDI_TASK_START_AP	Added a new task parameter: WDI_TLV_AP_BAND_CHANNEL.
OID_WDI_SET_ADAPTER_CONFIGURATION	Added a new task parameter: WDI_TLV_PLDR_SUPPORT.

Topic	Description
WDI_TLV_AP_BAND_CHANNEL	Newly added TLV type.
WDI_TLV_P2P_CAPABILITIES	Added a new value that specifies whether the adapter supports operating a GO on the 5GHz band.
WDI_TLV_PLDR_SUPPORT	Newly added TLV type.
WDI_TLV_START_AP_PARAMETERS	Added a new value that specifies whether to allow legacy SoftAP clients to connect. Added a new value that specifies whether the AP can only be started on the channels specified in OID_WDI_TASK_START_AP task parameters with **WDI_TLV_AP_BAND_CHANNEL**.

Windows 10

Initial version.

Native 802.11 IHV Extensions Topics

Article • 12/15/2021

This section describes how an independent hardware vendor (IHV) can add functionality to the Native 802.11 framework. For more information about the Native 802.11 framework, see Native 802.11 Software Architecture.

This section includes the following topics:

Overview of IHV Extensibility

Article • 12/15/2021

The Native 802.11 framework provides support for an independent hardware vendor (IHV) to add functionality to the Native 802.11 framework.

For example, the IHV can provide support for any of the following:

- Proprietary or non-standard authentication algorithms for port-based network access. For more information, see Extending Support for 802.11 Authentication Algorithms.

- Proprietary or non-standard cipher algorithms for data encryption. For more information, see Extending Support for 802.11 Cipher Algorithms.

- Proprietary PHY configurations. For more information, see Extending Support for 802.11 PHY Configurations.

In order to extend the Native 802.11 functionality, the IHV must provide the following components:

- A Native 802.11 miniport driver that supports the Extensible Station (ExtSTA) operation mode. For more information about this mode, see Extensible Station Operation Mode. For more information about ways the ExtSTA operation mode can extend Native 802.11 functionality, see Extending Native 802.11 Functionality.

- An IHV Extensions DLL, which processes the security packets exchanged through the proprietary authentication algorithms that the IHV supports. The IHV Extensions DLL is also responsible for cipher key derivation through these authentication algorithms, as well as the validation of user data that pertains to the security extensions supported by the IHV.

  For more information about the IHV Extensions DLL, see Native 802.11 IHV Extensions DLL.

- An IHV User Interface (UI) Extensions DLL, which extends the Native 802.11 user interface to configure connectivity and security settings that are validated and processed by the IHV Extensions DLL.

  For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

For more information about the modules provided by the IHV, see Native 802.11 Software Architecture.

To provide a secure execution environment, the IHV should do the following:

1. Do not log any sensitive information, such as encryption keys, in event or debug logs.

2. Use CryptProtectMemory to protect sensitive encryption keys stored in memory, and SecureZeroMemory to clear memory when done with the keys.

3. Treat the IHV extension portions of the network profile as untrusted data that may have been manipulated by an attacker. IHV extension portions of profiles are opaque to the 802.11 Auto Configuration Module (ACM) and Media Specific Module (MSM) and will not be validated. (See Native 802.11 Software Architecture for descriptions of these modules and configuration control paths.) This IHV extension data should be appropriately parsed to prevent any buffer overflows or attacks that could lead to a local escalation of privileges.

Installing Native 802.11 IHV Extensions

Article • 06/17/2022

To install the Native 802.11 IHV Extensions DLL and Native 802.11 IHV UI Extensions DLL, the independent hardware vendor (IHV) must make the following changes to the DDInstall section within the INF file that is used for the installation of the IHV's wireless LAN (WLAN) adapter.

- Add a CopyFiles directive, with an associated *file-list-section*, to the INF file. The name of each DLL developed by the IHV must be within the *file-list-section*.

  For example, if the IHV is installing IhvExt.dll and IhvUIExt.dll, the INF file would have the following CopyFiles directive and *file-list-section*:

  ```
  CopyFiles = Sample-File-List-Section

  [Sample-File-List-Section]
  IhvExt.dll,,,2
  IhvUIExt.dll,,,2
  ```

  For more information about the CopyFiles directive, see **INF CopyFiles Directive**.

- Make sure that a DestinationDirs section declares the destination of the *file-list-section* used in the CopyFiles directive.

  In the previous example, the DestinationDirs section would have the following values:

  ```
  [DestinationDirs]
  DefaultDestDir = 13
  Sample-File-List-Section = 13
  ```

  For more information about the DestinationDirs section, see **INF DestinationDirs Section**.

- Make sure that an AddReg directive, with an associated *add-registry-section*, is added to the INF file for each WLAN adapter. For more information about the AddReg directive, see **INF AddReg Directive**.

Within the *add-registry-section*, the following keys must be declared.

HKR, Ndi\IHVExtensions, ExtensibilityDLL, 0, *destination-file-name*
This key identifies the name of the IHV Extensions DLL. For example, to associate the IhvExt.dll with the management of the WLAN adapter, the following key would be declared.

```
HKR,Ndi\IHVExtensions, ExtensibilityDLL, 0, %13%\IhvExt.dll
```

HKR, Ndi\IHVExtensions, UIExtensibilityCLSID, 0, *CLSID*
This key identifies the COM class identifier (CLSID), which was registered on the target system for the IHV UI Extensions DLL. The *CLSID* value must be enclosed in quotation marks. This key associates the IHV UI Extensions DLL with the IHV Extensions DLL installed through the **ExtensibilityDLL** key.

Note The **UIExtensibilityCLSID** key is required only if the IHV installs an IHV UI Extensions DLL.

HKR, Ndi\IHVExtensions, AdapterOUI, 0x00010001, *OUI*
This key identifies the IEEE-assigned organizationally unique identifier (OUI), which identifies the IHV. The OUI value must be declared as a 24-bit hexadecimal value.

The AdapterOUI key is used to verify that the OUI of the WLAN adapter matches the value of the **OUI** attribute of the **IHV** XML element. For more information about the **IHV** element and the Native 802.11 XML schema, refer to the Microsoft Windows SDK documentation.

For more information about the INF file and its sections, see Creating an INF File.

Native 802.11 IHV Extensions DLL Topics

Article • 12/15/2021

This section discusses the IHV Extensions DLL and has the following topics:

Network Profile Management

Interaction with the User

Pre-Association Operations

Post-Association Operations

Send and Receive Operations

Notification Operations

Virtual Station

Native 802.11 IHV Extensions DLL Overview

Article • 12/15/2021

Through an IHV Extensions DLL, the independent hardware vendor (IHV) can support the following:

- Proprietary or non-standard authentication algorithms. Through this support, the IHV Extensions DLL sends and receives all security packets related to the authentication algorithm.

  The IHV Extensions DLL can also support standard authentication algorithms for network configurations that are not supported by the operating system. For example, the DLL can support the Wi-Fi Protected Access with preshared keys (WPA-PSK) authentication algorithm over independent basic service set (IBSS) networks, which is a configuration not supported by Windows Vista.

- Proprietary or non-standard cipher algorithms. Through this support, the IHV Extensions DLL is responsible for deriving the cipher key and downloading the keys to the Native 802.11 miniport driver.

  The IHV Extensions DLL can also support standard cipher algorithms for network configurations that are not supported by the operating system. For example, the DLL can support the Temporal Key Integrity Protocol (TKIP) over IBSS networks, which is a configuration not supported by Windows Vista.

- Verification of proprietary extensions to a network profile. For example, the IHV Extensions DLL is responsible for the validation of user settings for IHV-defined security options.

- Configuration of the Native 802.11 miniport driver. For example, prior to starting a connection operation with the miniport driver, the operating system will call the *Dot11ExtIhvPerformPreAssociate* function so that the IHV Extensions DLL can configure the driver with proprietary extensions related to the connection to a BSS network.

- Interface to the IHV UI Extensions DLL. Through this interface, the IHV Extensions DLL can request user input or notification. For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

The Native 802.11 IHV Extensibility Host process loads the IHV Extensions DLL into its process space upon the first arrival and detection of a wireless LAN (WLAN) adapter for which the DLL was installed. For more information about the Native 802.11 IHV Extensibility Host process and Native 802.11 framework, see Native 802.11 Software Architecture.

The Native 802.11 IHV Extensibility Host process provides an API through its IHV Extensibility functions. Through this API, the IHV Extensions DLL can interface the Native 802.11 miniport driver or IHV UI Extensions DLL. For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

Similarly, the IHV Extensions DLL provides an API through its IHV Handler functions. The Native 802.11 IHV Extensibility Host process uses this API for various operations, such as initiating pre- or post-association operations. For more information about the IHV Handler functions, see Native 802.11 IHV Handler Functions.

Native 802.11 IHV Extensibility functions

Article • 12/15/2021

ⓘ **Important**

The **Native 802.11 Wireless LAN** interface is deprecated in Windows 10 and later. Please use the WLAN Device Driver Interface (WDI) instead. For more information about WDI, see **WLAN Universal Windows driver model**.

The Native 802.11 IHV Extensibility functions are provided by the operating system and are called by the IHV Extensions DLL to do the following:

- Allocate and free buffers that are used within the Native 802.11 framework.
- Send packets, such as a packet defined by an authentication algorithm, through the IHV's wireless LAN (WLAN) adapter.
- Configure the IHV's WLAN adapter with various security settings for any authentication and cipher algorithms supported by the IHV Extensions DLL.
- Interface with the IHV UI Extensions DLL (if installed) to process event notifications. For example, the IHV Extensions DLL could notify the IHV UI Extensions DLL about the various stages involved in a basic service set (BSS) network connection.

For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

ⓘ **Note**

The IHV Extensions DLL calls each Native 802.11 IHV Extensibility function through a function pointer associated with a member of the **DOT11EXT_APIS** structure. When the operating system calls the **Dot11ExtIhvInitService** IHV Handler function, it passes the list of pointers to the IHV Extensibility functions through the *pDot11ExtAPI* parameter.

The following table lists the Native 802.11 IHV Extensibility Functions that can be called by the IHV Extensions DLL. Each IHV Extensibility function can only be called under these conditions.

- **Called After Service Initialization**
  The IHV Extensibility function can only be called after the Dot11ExtIhvInitService IHV Handler function has been called to initialize the IHV Extensions DLL. Also, the

Extensions DLL cannot call the IHV Extensibility function after the Dot11ExtIhvDeinitService IHV Handler function has been called.

- **Called after Adapter Initialization**
  The IHV Extensibility function can only be called after the Dot11ExtIhvInitAdapter IHV Handler function has been called to initialize the interface to the IHV's WLAN adapter.
  The IHV Extensibility function requires a handle, which identifies the WLAN adapter. When *Dot11ExtIhvInitAdapter* is called, the IHV Extensions DLL is passed this handle through the *hDot11SvcHandle* parameter.
  The Extensions DLL cannot call the IHV Extensibility function after the Dot11ExtIhvDeinitAdapter IHV Handler function has been called.
- **Called after Pre-Association**
  The IHV Extensibility function can only be called after the Dot11ExtIhvPerformPreAssociate IHV Handler function has been called to initiate a pre-association operation with a basic service set (BSS) network.
  The IHV Extensibility function requires a handle, which identifies the BSS network connection. When *Dot11ExtIhvPerformPreAssociate* is called, the IHV Extensions DLL is passed this handle through the *hConnection* parameter.
  The Extensions DLL cannot call the IHV Extensibility function after the Dot11ExtIhvDeinitAdapter or Dot11ExtIhvAdapterReset IHV Handler functions have been called.
- **Called after Post-Association**
  The IHV Extensibility function can only be called after the Dot11ExtIhvPerformPostAssociate IHV Handler function has been called to initiate a post-association operation with a basic service set (BSS) network.
  The IHV Extensibility function requires a handle, which identifies the security session with the BSS network connection. When *Dot11ExtIhvPerformPostAssociate* is called, the IHV Extensions DLL is passed this handle through the *hSecuritySessionID* parameter.
  The Extensions DLL cannot call the IHV Extensibility function after the Dot11ExtIhvDeinitAdapter or Dot11ExtIhvAdapterReset IHV Handler functions have been called.

Function	Called after service initialization	Called after adapter initialization	Called after pre-association	Called after post-association
Dot11ExtAllocateBuffer	X			
Dot11ExtFreeBuffer	X			
Dot11ExtGetProfileCustomUserData			X	

Function	Called after service initialization	Called after adapter initialization	Called after pre-association	Called after post-association
Dot11ExtNicSpecificExtension		X		
Dot11ExtStartOneX				X
Dot11ExtStopOneX				X
Dot11ExtPostAssociateCompletion				X
Dot11ExtPreAssociateCompletion			X	
Dot11ExtProcessOneXPacket				X
Dot11ExtQueryVirtualStationProperties		X		
Dot11ExtReleaseVirtualStation		X		
Dot11ExtRequestVirtualStation		X		
Dot11ExtSendNotification		X		
Dot11ExtSendUIRequest		X		
Dot11ExtSetAuthAlgorithm		X		
Dot11ExtSetCurrentProfile			X	
Dot11ExtSetDefaultKey		X		
Dot11ExtSetDefaultKeyId		X		
Dot11ExtSetEtherTypeHandling		X		
Dot11ExtSetExcludeUnencrypted		X		
Dot11ExtSetKeyMappingKey		X		
Dot11ExtSetMulticastCipherAlgorithm		X		
Dot11ExtSetProfileCustomUserData		X		
Dot11ExtSetUnicastCipherAlgorithm		X		
Dot11ExtSetVirtualStationAPProperties			X	

For more information about IHV Handler functions, see Native 802.11 IHV Handler Functions.

Native 802.11 IHV Handler functions

Article • 12/15/2021

ⓘ **Important**

The **Native 802.11 Wireless LAN** interface is deprecated in Windows 10 and later. Please use the WLAN Device Driver Interface (WDI) instead. For more information about WDI, see **WLAN Universal Windows driver model**.

The Native 802.11 IHV Handler functions are provided by the IHV Extensions DLL and are called by the operating system to do the following:

- Allocate and free buffers that are used within the Native 802.11 framework.
- Send packets, such as a packet defined by an authentication algorithm, through the IHV's wireless LAN (WLAN) adapter.
- Receive packets based on a specified list of IEEE EtherType values and privacy exemption rules.
- Configure the IHV's WLAN adapter with various security settings for any proprietary authentication and cipher algorithms.
- Interface with the IHV UI Extensions DLL (if installed) to process event notifications. For example, the IHV Extensions DLL could notify the UI Extensions DLL about the various stages involved in a basic service set (BSS) network connection.

For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

ⓘ **Note**

With the exception of **Dot11ExtIhvGetVersionInfo** and **Dot11ExtIhvInitService**, the operating system calls the IHV Handler functions through a function pointer associated with a member of the **DOT11EXT_IHV_HANDLERS** structure. When the operating system calls the *Dot11ExtIhvInitService* IHV Handler function, the IHV Extensions DLL returns the list of pointers to the IHV Handler functions through the *pDot11IHVHandlers* parameter.

This section describes the following Native 802.11 IHV Handler functions.

- Dot11ExtIhvAdapterReset
- Dot11ExtIhvControl
- Dot11ExtIhvCreateDiscoveryProfiles

- Dot11ExtIhvDeinitAdapter
- Dot11ExtIhvDeinitService
- Dot11ExtIhvGetVersionInfo
- Dot11ExtIhvInitAdapter
- Dot11ExtIhvInitService
- Dot11ExtIhvInitVirtualStation
- Dot11ExtIhvIsUIRequestPending
- Dot11ExtIhvOneXIndicateResult
- Dot11ExtIhvPerformCapabilityMatch
- Dot11ExtIhvPerformPostAssociate
- Dot11ExtIhvPerformPreAssociate
- Dot11ExtIhvProcessSessionChange
- Dot11ExtIhvProcessUIResponse
- Dot11ExtIhvQueryUIRequest
- Dot11ExtIhvReceiveIndication
- Dot11ExtIhvReceivePacket
- Dot11ExtIhvSendPacketCompletion
- Dot11ExtIhvStopPostAssociate
- Dot11ExtIhvValidateProfile

Native 802.11 IHV Extensions DLL Implementation Guidelines

Article • 12/06/2022

The IHV Extensions DLL is implemented as a run-time dynamic-link library (DLL). For more information about DLLs, see About Dynamic-Link Libraries.

Refer to the following guidelines when implementing an IHV Extensions DLL.

- The structures and function prototypes referenced by the IHV Extensions DLL are declared in Wlanihv.h.
- The IHV Extensions DLL must implement the *Dot11ExtIhvGetVersionInfo* and *Dot11ExtIhvInitService* functions. Also, these functions must be exported through the module-definition (.def) file used to build the DLL. The operating system resolves the address for these functions through the **GetProcAddress** function.
- The IHV Extensions DLL must implement all of the IHV Handler functions. The DLL returns a list of function pointers to these functions when the operating system calls the *Dot11ExtIhvInitService* function.

  For more information about the IHV Handler functions, see Native 802.11 IHV Handler Functions.
- For Windows Vista, the IHV Extensions DLL must support the interface version of zero. When *Dot11ExtIhvGetVersionInfo* is called, the DLL must define the minimum and maximum supported interface versions to be zero.

DLL Start/Stop Operations Topics

Article • 12/15/2021

This section discusses how the operating system starts and stops the IHV Extensions DLL, and includes the following topics:

DLL Start Operations

DLL Stop Operations

DLL Start Operations

Article • 12/15/2021

Immediately after loading the IHV Extensions DLL, the operating system calls the following IHV Handler functions in this sequence.

1. The operating system calls the *Dot11ExtIhvGetVersionInfo* IHV Handler function to determine the interface versions supported by the IHV Extensions DLL. This function is passed a pointer to a **DOT11_IHV_VERSION_INFO** structure, which the DLL formats with the minimum and maximum interface versions that it supports. **Note** For Windows Vista, the IHV Extensions DLL must set the **dwVerMin** and **dwVerMax** members of the DOT11_IHV_VERSION_INFO structure to zero.

2. If the IHV Extensions DLL supports an interface version that is supported by the operating system, the operating system calls the *Dot11ExtIhvInitService* IHV Handler function to initialize the DLL.

The IHV Extensions DLL must follow these guidelines when *Dot11ExtIhvInitService* is called.

- The *pDot11ExtAPI* parameter contains a pointer to a **DOT11EXT_APIS** structure, which is formatted with the addresses of the IHV Extensibility functions supported by the operating system. The IHV Extensions DLL must copy the DOT11EXT_APIS structure, which is referenced by the *pDot11ExtAPI* parameter, to a globally-declared DOT11EXT_APIS structure.

- The *pDot11IHVHandlers* parameter contains a pointer to a **DOT11EXT_IHV_HANDLERS** structure, which the IHV Extensions DLL formats with the addresses of the IHV Handler functions that it supports. **Note** The DLL must not set any of the members of the DOT11EXT_IHV_HANDLERS structure to **NULL**.

- The IHV Extensions DLL should perform any internal initialization and resource allocation in preparation for calls to its IHV Handler functions after the DLL returns from *Dot11ExtIhvInitService*.

For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

For more information about the IHV Handler functions, see Native 802.11 IHV Handler Functions.

DLL Stop Operations

Article • 12/06/2022

The operating system stops and unloads the IHV Extensions DLL whenever.

- The last wireless LAN (WLAN) adapter managed by the DLL is either removed or disabled.
- The host computer is reset or shut down.

The operating system follows this sequence when stopping and unloading the IHV Extensions DLL.

1. The operating system first calls the *Dot11ExtIhvDeinitAdapter* IHV Handler function for every WLAN adapter managed by the IHV Extensions DLL. For more information about this operation, see 802.11 WLAN Adapter Removal.

   After the call to *Dot11ExtIhvDeinitAdapter*, the IHV Extensions DLL must not call any IHV Extensions function related to adapter-specific operations, such as **Dot11ExtNicSpecificExtension**.

2. The operating system then calls the *Dot11ExtIhvDeinitService* IHV Handler function. When this function is called, the IHV Extensions DLL must free all allocated resources and prepare itself for unloading.

   After the call to *Dot11ExtIhvDeinitService*, the IHV Extensions DLL must not call any IHV Extensions function.

3. Finally, the operating system calls the *DllMain* function in the IHV Extensions DLL with the *fdwReason* parameter set to DLL_PROCESS_DETACH. For more information about *DllMain* and DLLs, see About Dynamic-Link Libraries.

For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

802.11 WLAN Adapter Management Topics

Article • 12/15/2021

This section discusses wireless LAN (WLAN) adapter management by the IHV Extensions DLL, and includes the following topics:

802.11 WLAN Adapter Arrival

802.11 WLAN Adapter Removal

802.11 WLAN Adapter Reset

802.11 WLAN Adapter Communication Channel

802.11 WLAN Adapter Arrival

Article • 12/15/2021

When the operating system detects a wireless LAN (WLAN) adapter for which an IHV Extensions DLL has been installed, the operating system calls the *Dot11ExtIhvInitAdapter* IHV Handler function. The operating system calls this function whenever a WLAN adapter becomes available and enabled for use, such as when a PCMCIA adapter is inserted.

When the *Dot11ExtIhvInitAdapter* function is called, the IHV Extensions DLL does the following:

- Allocates an array for the WLAN adapter context data, as well as any resources the DLL needs for the WLAN adapter.

- Registers a list of IEEE EtherTypes for the security packets received and consumed by the IHV Extensions DLL.

- Configures the adapter with any proprietary settings defined by the IHV.

The IHV Extensions DLL must follow these guidelines when *Dot11ExtIhvInitAdapter* is called.

- The *hDot11SvcHandle* parameter contains a unique handle value assigned by the operating system for the WLAN adapter. The IHV Extensions DLL must save this handle value and pass it to the *hDot11SvcHandle* parameter of the IHV Extensibility functions related to the adapter-specific processing, such as **Dot11ExtSetKeyMappingKey**.

  Typically, the DLL saves this handle value within a member of its WLAN adapter context array.

- The IHV Extensions DLL must return a unique handle value for the WLAN adapter through the *phIhvExtAdapter* parameter. The operating system passes the handle value to the *hIhvExtAdapter* parameter of the IHV Handler functions related to the adapter-specific processing, such as *Dot11ExtIhvReceiveIndication*.

  Typically, the DLL returns the address of the WLAN adapter context array as the handle value.

- The IHV Extensions DLL calls **Dot11ExtSetEtherTypeHandling** to register a list of the IEEE EtherTypes for the security packets that the DLL will receive. The IHV

Extensions DLL can also specify a list of EtherTypes that will be excluded from payload decryption. For more information about registering EtherTypes, see IEEE EtherType Handling.

After EtherTypes are registered, the operating system calls the *Dot11ExtIhvReceivePacket* IHV Handler function for every packet whose EtherType matches an entry in the list.

- The operating system configures the adapter with standard 802.11 parameters through set requests of the Native 802.11 object identifiers (OIDs). For more information about these OIDs, see Native 802.11 Wireless LAN OIDs.

  However, the DLL can configure the adapter with proprietary parameters through calls to the **Dot11ExtNicSpecificExtension** function. Through this function call, the DLL can communicate directly with the Native 802.11 miniport driver that manages the WLAN adapter and issue query or set requests to the driver based on a proprietary format defined by the IHV.

  For more information about the interface through which the DLL and WLAN adapter communicate, see 802.11 WLAN Adapter Communication Channel.

802.11 WLAN Adapter Removal

Article • 12/15/2021

When a wireless LAN (WLAN) adapter is removed or disabled, the operating system calls *Dot11ExtIhvDeinitAdapter* to notify the IHV Extensions DLL of the adapter's removal. The operating system also calls the *Dot11ExtIhvDeinitAdapter* function for every adapter managed by the IHV Extensions DLL before the operating system unloads the DLL.

When *Dot11ExtIhvDeinitAdapter* is called, the IHV Extensions DLL must follow these guidelines.

- The IHV Extensions DLL must free any allocated resources for the WLAN adapter. In particular, all memory allocated through calls to **Dot11ExtAllocateBuffer** must be freed through calls to **Dot11ExtFreeBuffer**.

- The handle used by the operating system to reference the WLAN adapter is no longer valid when *Dot11ExtIhvDeinitAdapter* is called. The operating system passes its handle to the IHV Extensions DLL through the *hDot11SvcHandle* parameter when *Dot11ExtIhvInitAdapter* is called.

  Within the call to the *Dot11ExtIhvDeinitAdapter* function and after returning from the call, the DLL must not use the handle value when calling any IHV Extensibility function that declares an *hDot11SvcHandle* parameter, such as **Dot11ExtSendPacket**.

- If the IHV Extensions DLL had a pending pre-association operation, which was initiated through a call to the *Dot11ExtIhvPerformPreAssociate* IHV Handler function, the operating system regards the operation as canceled through the call to the *Dot11ExtIhvDeinitAdapter* function. Within the call, the DLL must cancel the pre-association operation internally but must not call **Dot11ExtPreAssociateCompletion** to complete the pre-association operation.

  For more information about the pre-association operation, see Pre-Association Operations.

- If the IHV Extensions DLL had a pending post-association operation, which was initiated through a call to the *Dot11ExtIhvPerformPostAssociate* IHV Handler function, the operating system cancels the operation by calling the *Dot11ExtIhvStopPostAssociate* function before it calls *Dot11ExtIhvDeinitAdapter*.

For more information about the post-association operation, see Post-Association Operations.

- The operating system calls the *Dot11ExtIhvDeinitAdapter* function for every adapter managed by the IHV Extensions DLL before the operating system unloads the DLL. In this situation, the operating system calls the *Dot11ExtIhvDeinitService* IHV Handler function after the last WLAN adapter has been halted through a call to *Dot11ExtIhvDeinitAdapter*.

  For more information about this operation, see DLL Stop Operations.

802.11 WLAN Adapter Reset

Article • 12/15/2021

The operating system calls *Dot11ExtIhvAdapterReset* whenever it becomes necessary to restore the wireless LAN (WLAN) adapter to its initialized state. The operating system calls this function whenever one of the following events occurs.

- The WLAN adapter performs a disconnection operation. For more information about this operation, see Disconnection Operations.
- The operating system resets the Native 802.11 miniport driver, which manages the adapter, through a set request of OID_DOT11_RESET_REQUEST.

When *Dot11ExtIhvAdapterReset* is called, the IHV Extensions DLL must follow these guidelines.

- The IHV Extensions DLL must restore its state to the same state it was in after the *Dot11ExtIhvInitAdapter* function was called. If the DLL configured proprietary settings on the WLAN adapter, it must restore these settings to the same state they were in after *Dot11ExtIhvInitAdapter* was called.
- If the IHV Extensions DLL had a pending pre-association operation, which was initiated through a call to the *Dot11ExtIhvPerformPreAssociate* IHV Handler function, the DLL must call **Dot11ExtPreAssociateCompletion** to cancel the operation. In this situation, the DLL sets the *dwWin32Error* parameter of **Dot11ExtPreAssociateCompletion** to ERROR_CANCELLED.

  For more information about the pre-association operation, see Pre-Association Operations.
- If the DLL had a pending post-association operation, which was initiated through a call to the *Dot11ExtIhvPerformPostAssociate* IHV Handler function, the DLL must call **Dot11ExtPostAssociateCompletion** to cancel the operation. In this situation, the DLL sets the *dwWin32Error* parameter of **Dot11ExtPostAssociateCompletion** to ERROR_CANCELLED.

  For more information about the post-association operation, see Post-Association Operations.

802.11 WLAN Adapter Communication Channel

Article • 12/15/2021

The operating system provides a pass-through communication channel between the IHV Extensions DLL and the Native 802.11 miniport driver. The IHV Extensions DLL accesses the communication channel for the following operations.

Sending/Receiving Proprietary Configuration Data
The IHV Extensions DLL sends NDIS 6.0 or later object identifier (OID) method requests to the Native 802.11 miniport driver through calls to the **Dot11ExtNicSpecificExtension** function. Internally, this function issues a method request of OID_DOT11_NIC_SPECIFIC_EXTENSION to the miniport driver. For more information about NDIS OID method requests, see **NDIS_OID_REQUEST**.

Typically, the IHV Extensions DLL calls **Dot11ExtNicSpecificExtension** to do the following:

- Set proprietary configuration parameters for the miniport driver or WLAN adapter.
- Query proprietary configuration parameters or status data from the miniport driver or WLAN adapter.

Receiving Notifications/Indications
The IHV Extensions DLL asynchronously receives notifications from the Native 802.11 miniport driver through calls to the *Dot11ExtIhvReceiveIndication* IHV Handler function. The operating system calls this function whenever the miniport driver makes a media-specific indication through a call to **NdisMIndicateStatusEx**. For more information about this type of indication, see **NDIS_STATUS_MEDIA_SPECIFIC_INDICATION**.

Sending 802.11 Packets
The IHV Extensions DLL sends 802.11 packets to the Native 802.11 miniport driver through calls to the **Dot11ExtSendPacket** function. The miniport driver queues the packet on the WLAN adapter for transmission. When the packet has been transmitted, the operating system calls the *Dot11ExtIhvSendPacketCompletion* IHV Handler function. For more information about sending packets by the IHV Extensions DLL, see Send Operations.

Typically, the IHV Extensions DLL calls **Dot11ExtSendPacket** to send security packets during the post-association operation. The security packets are based on the authentication algorithm supported by the DLL and enabled on the WLAN adapter.

Receiving 802.11 Packets

The IHV Extensions DLL receives 802.11 packets from the Native 802.11 miniport driver through calls to the *Dot11ExtIhvReceivePacket* function. The operating system calls this function for every received packet that has an IEEE EtherType that matches an entry in the list of EtherTypes registered by the DLL through a call to **Dot11ExtSetEtherTypeHandling**. For more information about receiving packets by the IHV Extensions DLL, see Receive Operations.

The following points apply to the communication channel between the IHV Extensions DLL and the Native 802.11 miniport driver.

- Configuration, notification, or indication data transferred over this channel has a format defined by the independent hardware vendor (IHV), which is opaque to the operating system.
- All data received through this channel is serialized and delivered in the order the data was sent by the IHV Extensions DLL or Native 802.11 miniport driver.

Network Profile Management

Article • 12/06/2022

This section discusses the management and processing of network profiles by the IHV Extensions DLL. Network profiles define the attributes for the connection operation to a basic service (BSS) network.

The IHV Extensions DLL is responsible for verifying or creating proprietary extensions to a network profile. These extensions are XML data fragments, with each fragment declared within an **IHV** element of the Native 802.11 XML schema. The data within the <IHV> and </IHV> tags of the **IHV** element is in a format defined by the IHV.

This section includes the following topics:

Network Profile Overview

Creating Network Profile Extensions

Validating Network Profile Extensions

Network Profile Overview

Article • 12/06/2022

A network profile defines the attributes for a connection to a basic service set (BSS) network. Network profiles consist of XML data fragments. For Windows Vista, a network profile contains the following XML fragments.

Profile Name (required)
The name of the network profile, which is the service set identifier (SSID) of the BSS network.

Standard 802.11 Connectivity Settings (required)
This XML fragment consists of standard 802.11 settings for network connectivity, such as the BSS network type (infrastructure or independent) or type of wireless LAN (WLAN) security. The operating system processes the standard connectivity settings and configures the wireless WLAN adapter with them.

IHV Connectivity Extensions (optional)
This XML fragment consists of the extensions to network connectivity as defined by the IHV. The operating system passes the connectivity extensions to the IHV Extensions DLL for processing. The DLL is responsible for configuring the WLAN adapter with the proprietary extensions.

Standard 802.11 Security Settings (optional)
This XML fragment consists of the standard 802.11 authentication and cipher settings, such as the type of authentication and cipher algorithm to use on the BSS network connection. The operating system processes the standard security settings and configures the WLAN adapter with them.

IHV Security Extensions (optional)
This XML fragment consists of the extensions to network security as defined by the IHV. The IHV extensions can specify either of the following:

- Standard security settings.

  For the WLAN adapter that is managed by the IHV Extensions DLL, the DLL is responsible for the security algorithms, such as the Robust Security Network Association (RSNA) authentication algorithm or the AES-CCMP cipher algorithm. The operating system is no longer responsible. In this situation, the IHV Extensions DLL can either process the algorithms or provide proprietary methods for offloading the processing to the WLAN adapter.

- Proprietary security settings.

  The IHV Extensions DLL can provide support for security algorithms not supported by the operating system, such as non-standard or proprietary algorithms. The DLL is responsible for processing the algorithms or provide proprietary methods for offloading the processing to the WLAN adapter.

Creating Network Profile Extensions

Article • 12/15/2021

After the underlying wireless LAN (WLAN) adapter completes a scan operation, it returns a list of the detected basic service set (BSS) network to the operating system. The operating system calls the *Dot11ExtIhvCreateDiscoveryProfiles* function for every BSS network for which the user has not created a network profile. When this function is called, the IHV Extensions DLL can return temporary connectivity and security profile fragments that could be used to connect to the BSS network.

For more information about the scan operation, see Native 802.11 Scan Operations.

When *Dot11ExtIhvCreateDiscoveryProfiles* is called, the IHV Extensions DLL must follow these guidelines.

- The operating system passes to the *pConnectableBssid* parameter a list of IEEE 802.11 Beacon and Probe Response frames received during the last scan operation. This list is formatted as a DOT11_BSS_ENTRY structure. Each Beacon or Probe response within the list was sent by an access point (AP) with the same service set identifier (SSID).

  Note For Windows Vista, the IHV Extensions DLL supports only infrastructure basic service set (BSS) networks.

  The IHV Extensions DLL must parse each of the fixed-length fields and variable-length information elements (IEs) in order to create the appropriate profile fragments.

- The connectivity and security profile fragment must contain valid settings that can be used to connect to each of the APs, whose BSS identifiers (BSSIDs) are referenced through the *pConnectableBssid* parameter.

- Each connectivity and security profile fragment contains the XML data for the profile extensions defined by the IHV. The XML data within the profile fragment must be delimited by <IHV> and </IHV> tags.

Validating Network Profile Extensions

Article • 12/15/2021

The operating system calls IHV Handler functions to validate IHV-defined connectivity and security settings under the following conditions.

- The user creates a new network profile that contains settings for the IHV-defined connectivity and/or security profile extensions. In this situation, the operating system calls the *Dot11ExtIhvValidateProfile* IHV Handler function to validate the user settings.

- The WLAN adapter completes a scan operation and returns its results to the operating system. The operating system calls the *Dot11ExtIhvPerformCapabilityMatch* IHV Handler function to determine whether a detected basic service set (BSS) network matches the IHV-defined connectivity and security settings from a network profile.

  The operating system passes a list of the 802.11 Beacon and Probe Response frames from the BSS network to the *pConnectableBssid* parameter of the **Dot1ExtIhvPerformCapabilityMatch** function. The operating system also passes the connectivity and security profile extensions to the *pIhvConnProfile* and *pIhvSecProfile* parameters, respectively.

  If all of the entries in the list of 802.11 Beacon and Probe Response frames advertise the connectivity and security attributes defined in the profile fragments, the *Dot11ExtIhvPerformCapabilityMatch* function returns ERROR_SUCCESS.

- The operating system initiates a pre-association operation by calling the *Dot11ExtIhvPerformPreAssociate* function. In this situation, the IHV Extensions DLL must verify that the connectivity and security settings are valid. If the settings are valid, the function returns ERROR_SUCCESS and the DLL proceeds with the pre-association operation. Otherwise, the function returns an appropriate error code as defined in Winerror.h.

  For more information about the pre-association operation, see Pre-Association Operations.

For more information about the IHV Handler functions, see Native 802.11 IHV Handler Functions.

Interaction with the User

Article • 12/15/2021

The IHV Extensions DLL does not provide a user interface (UI) component. Instead, it interfaces with the IHV UI Extensions DLL to display the appropriate UI pages to the user. For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

This section discusses the ways in which the IHV Extensions DLL requests user interaction, and includes the following topics:

Requesting User Interaction

Processing Session Changes

Requesting User Interaction

Article • 12/15/2021

At any time after the call to *Dot11ExtIhvInitAdapter*, the IHV Extensions DLL can request interaction with the user by calling the **Dot11ExtSendUIRequest** function. The operating system forwards all user interaction requests to the IHV UI Extensions DLL, which will process the request and display the appropriate user interface (UI) pages to the user.

When the request has been completed, the operating system calls the *Dot11ExtIhvProcessUIResponse* function to forward the results from the IHV UI Extensions DLL for the user interaction. For more information about the IHV UI Extensions DLL, see Native 802.11 IHV UI Extensions DLL.

For example, the IHV Extensions DLL can request user interaction for any of the following.

- Notify the user regarding the stages of a pre or post-association operation.
- Prompt the user to enter his/her credentials for authentication during the post-association operation.

When it calls the **Dot11ExtSendUIRequest** function, the IHV Extensions DLL passes a pointer to a **DOT11EXT_IHV_UI_REQUEST** structure to the *pIhvUIRequest* parameter. The DOT11EXT_IHV_UI_REQUEST structure specifies the request, such as the globally unique ID (GUID), which identifies the UI request as well as the COM class ID (CLSID) of the target UI page that will handle this request.

When the IHV UI Extensions DLL has completed the user notification, the operating system calls the *Dot11ExtIhvProcessUIResponse* function. If the user had entered any data through the notification, the operating system passes a pointer to the buffer, which contains the data, to the *pvResponseBuffer* parameter.

The operating system might periodically query the status of pending notification requests. In this situation, the operating system calls the *Dot11ExtIhvIsUIRequestPending* and passes the GUID of the UI request to the *guidUIRequest* parameter.

When calling **Dot11ExtSendUIRequest**, the IHV Extensions DLL must follow these guidelines.

- The IHV Extensions DLL does not need to serialize the calls to **Dot11ExtSendUIRequest**. The DLL can have more than one pending UI request at any time.

- The UI request for a particular GUID is completed only when *Dot11ExtIhvProcessUIResponse* is called for that GUID. In this situation, the IHV Extensions DLL must not free any allocated resources for the UI request until *Dot11ExtIhvProcessUIResponse* is called.

- All pending UI requests are canceled whenever *Dot11ExtIhvAdapterReset* or *Dot11ExtIhvDeinitAdapter* is called. All pending UI requests are also canceled whenever *Dot11ExtIhvProcessSessionChange* is called with the *uEventType* parameter set to WTS_SESSION_LOGOFF.

  In these situations, the IHV Extensions DLL must free all allocated resources for each pending UI request.

The operating system can initiate user interaction itself whenever the connection state changes on the basic service set (BSS) network. In this situation, the operating system calls the *Dot11ExtIhvQueryUIRequest* function. The IHV Extensions DLL allocates a buffer and formats it as a **DOT11EXT_IHV_UI_REQUEST** structure. The DLL sets the members of the DOT11EXT_IHV_UI_REQUEST structure to reference a UI page that is appropriate for the change in connection status. The operating system is responsible for displaying the UI page.

Note The IHV Extensions must allocate the buffer that contains the **DOT11EXT_IHV_UI_REQUEST** structure through **Dot11ExtAllocateBuffer**. The DLL must not free the buffer after returning from *Dot11ExtIhvQueryUIRequest*.

Processing Session Changes

Article • 12/15/2021

If the user's session changes state, such as when the user logs in or out, the operating system notifies the IHV Extensions DLL about the session change by calling the *Dot11ExtIhvProcessSessionChange* function. The operating system passes the reason for the session change to the *uEventType* parameter.

If the *uEventType* parameter is set to WTS_SESSION_LOGOFF, the user has logged off of the current session. In this situation, all pending user interface (UI) requests must be canceled internally by the IHV Extensions DLL, and the DLL must free any allocated resources for each pending UI request.

Pre-Association Operations Topics

Article • 12/15/2021

This section discusses the pre-association operation and how it is performed by the IHV Extensions DLL. This section has the following topics:

Pre-Association Operation Overview

Pre-Association Operation Guidelines

Pre-Association Operation Overview

Article • 12/15/2021

After the user has selected a profile for a basic service set (BSS) network connection, the operating system calls the *Dot11ExtIhvPerformPreAssociate* function to initiate a pre-association operation. When this function is called, the IHV Extensions DLL does the following:

- Verifies the IHV-defined extensions to the connectivity and security profile.

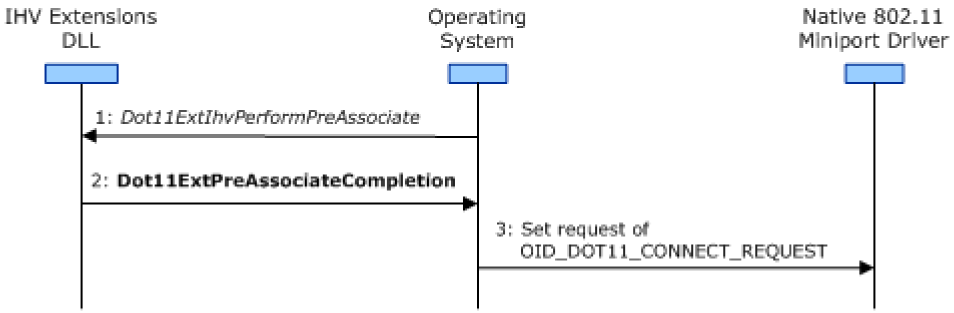
  If the IHV Extensions DLL determines that the profile is incorrect, it returns the appropriate error code as defined in Winerror.h. In this situation, the operating system notifies the user that the network profile cannot be used.

- Initiates the pre-association operation based on the IHV-defined extensions to the connectivity and security profiles.

  After the pre-association operation is initiated, it must be completed asynchronously from the call to *Dot11ExtIhvPerformPreAssociate*.

The IHV Extension DLL completes the pre-association operation through a call to **Dot11ExtPreAssociateCompletion**. Following this call, the operating system initiates the connection operation by issuing a set request of OID_DOT11_CONNECT_REQUEST to the Native 802.11 miniport driver, which manages the WLAN adapter.

The following figure shows the steps involved during the pre-association operation.



IHV Extensions DLL
Operating System
Native 802.11 Miniport Driver
1: Dot11ExtIhvPerformPreAssociate
2: Dot11ExtPreAssociateCompletion
3: Set request of OID_DOT11_CONNECT_REQUEST

When *Dot11ExtIhvPerformPreAssociate* is called, the operating system passes the IHV-defined extensions to the connectivity and security profile through the following parameters.

pIhvProfileParams
This parameter is passed a pointer to a **DOT11EXT_IHV_PROFILE_PARAMS** structure, which specifies the attributes of the basic service set (BSS) network to which the network

profile will be applied. For example, the **DOT11EXT_IHV_PROFILE_PARAMS** structure specifies the service set identifier (SSID) and type of the BSS network.

pIhvConnProfile
This parameter is passed a pointer to a DOT11EXT_IHV_CONNECTIVITY_PROFILE structure that contains the settings for the connectivity profile. The operating system only passes the extensions to the connectivity profile defined by the IHV and selected by the user.

pIhvSecProfile
This parameter is passed a pointer to a DOT11EXT_IHV_SECURITY_PROFILE structure that contains the settings for the security profile. The operating system only passes the extensions to the security profile defined by the IHV and selected by the user.

pConnectableBssid
This parameter is passed a pointer to a DOT11_BSS_LIST structure, which contains one or more 802.11 Beacon or Probe Response frames for the service set identifier (SSID) of the BSS network with which the DLL will perform the pre-association operation.

When performing the pre-association operation, the IHV Extensions DLL can do the following:

- Call the Dot11ExtNicSpecificExtension function to issue proprietary configuration requests for network connectivity to the Native 802.11 miniport driver.

  Through the *pIhvConnProfile* and *pIhvProfileParams* parameters, the IHV Extensions DLL can determine which proprietary connectivity settings were selected by the user.

  Through the *pConnectableBssid* parameter, the IHV Extensions DLL can determine the attributes of the BSS network and can configure proprietary network settings accordingly.

- Configure the WLAN adapter with the proprietary authentication and cipher algorithms to be used over the BSS network connection.

  Through the *pszXmlFragmentIhvSecurity* parameter, the IHV Extensions DLL can determine which proprietary security algorithms were selected by the user.

  The following IHV Extensibility functions can be called to set the security algorithms.
  - Dot11ExtSetAuthAlgorithm
  - Dot11ExtSetUnicastCipherAlgorithm
  - Dot11ExtSetMulticastCipherAlgorithm

- Call the **Dot11ExtSendUIRequest** function to request that the IHV UI Extensions DLL prompt the user for security parameters, such as the user's credentials.
- Call the **Dot11ExtSetEtherTypeHandling** function to register a list of the IEEE EtherTypes for the security packets that the DLL will receive. After the list is registered, the operating system calls the *Dot11ExtIhvReceivePacket* IHV Handler function for every packet whose EtherType matches an entry in the list.

  The IHV Extensions DLL can also specify a list of EtherTypes that will be excluded from payload decryption. For more information about registering EtherTypes, see IEEE EtherType Handling.
- Call the **Dot11ExtSetProfileCustomUserData** function to save data in the registry that is specific to the user and current BSS network profile.
- Call the **Dot11ExtGetProfileCustomUserData** function to retrieve data from the registry that is specific to the user and current BSS network profile.

For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

For more information about connection operations with BSS networks, see Connection Operations.

Pre-Association Operation Guidelines

Article • 12/15/2021

The IHV Extensions DLL must follow these guidelines when performing the pre-association operation.

- When the *Dot11ExtIhvPerformPreAssociate* function is called, the IHV Extensions DLL must do the following:
    - Verify the IHV extensions for the connectivity and security profile. If the profile parameters are invalid, the *Dot11ExtIhvPerformPreAssociate* function returns an appropriate error code as defined in Winerror.h.
    - Create and begin a new thread for the completion of the pre-association operation. Because the pre-association operation must be completed asynchronously from the call to *Dot11ExtIhvPerformPreAssociate*, the IHV Extensions DLL must call **Dot11ExtPreAssociateCompletion** from this thread after the operation completes.
    - Return ERROR_SUCCESS from the function call. At this point, the operating system is notified that the network profile is valid and the pre-association operation is in progress.

- The IHV Extensions DLL can call the **Dot11ExtNicSpecificExtension** function to configure the wireless LAN (WLAN) adapter. This function can be called either from within the call to *Dot11ExtIhvPerformPreAssociate* or from the thread that handles the pre-association operation after *Dot11ExtIhvPerformPreAssociate* returns.

- Calls to the **Dot11ExtSetProfileCustomUserData**, **Dot11ExtGetProfileCustomUserData**, and **Dot11ExtSetCurrentProfile** must not be made from within the call to *Dot11ExtIhvPerformPreAssociate*. These functions can only be called after *Dot11ExtIhvPerformPreAssociate* returns ERROR_SUCCESS.

- After the IHV Extensions DLL calls **Dot11ExtPreAssociateCompletion** to complete the pre-association operation, the handle for the connection session is no longer valid. The operating system passes this handle through the *hConnectSession* parameter of *Dot11ExtIhvPerformPreAssociate*. The DLL must not use this handle value when calling any IHV Extensibility functions that declare an *hConnectSession* parameter.

    For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

- If the *Dot11ExtIhvAdapterReset* function is called, the IHV Extensions DLL must cancel the pre-association operation by calling **Dot11ExtPreAssociateCompletion**. For more information about the reset operation, see 802.11 WLAN Adapter Reset.

- If the *Dot11ExtIhvDeinitAdapter* function is called, the IHV Extensions DLL must cancel the pre-association operation internally. However, it must not call any of the IHV Extensibility functions that can be called only after adapter initialization, including **Dot11ExtPreAssociateCompletion**.

Post-Association Operations Overview

Article • 12/15/2021

When the wireless LAN (WLAN) adapter successfully completes an association operation with an access point (AP), the operating system creates a data port for the association. The operating system then initiates a post-association operation on the data port by calling the *Dot11ExtIhvPerformPostAssociate* function.

Note For Windows Vista, the IHV Extensions DLL supports only infrastructure basic service set (BSS) networks.

When performing the post-association operation, the IHV Extensions DLL can do the following:

- Allocate any resources needed for the new data port.
- Perform proprietary security processing for the data port, including sending and receiving packets for the authentication algorithm configured during the pre-association operation. For more information about this operation, see Pre-Association Operations.
- Derive cipher keys and download them to the WLAN adapter.

When the WLAN adapter completes a disassociation operation with the AP, the operating system terminates the post-association operation on the data port by calling the *Dot11ExtIhvStopPostAssociate* function. Following this call, the operating system deletes the data port for the association.

The following topics describe what the IHV Extensions DLL must do to perform or stop a post-association operation.

Performing a Post-Association Operation

Stopping a Post-Association Operation

Interface to the Native 802.11 802.1X Module

For more information about the association operation, see Association Operations.

For more information about the disassociation operation, see Disassociation Operations.

For more information about the procedures involved in port management, see Port-Based Network Access.

Performing a Post-Association Operation

Article • 12/15/2021

When the wireless LAN (WLAN) adapter successfully completes an 802.11 association operation with an access point (AP), the Native 802.11 miniport driver notifies the operating system by making an NDIS_STATUS_DOT11_ASSOCIATION_COMPLETION indication. For more information about the association operation, see Association Operations.

Note For Windows Vista, the IHV Extensions DLL supports only infrastructure basic service set (BSS) networks.

After the operating system receives the NDIS_STATUS_DOT11_ASSOCIATION_COMPLETION indication, it calls the *Dot11ExtIhvPerformPostAssociate* function to notify the IHV Extensions DLL of the following:

- The creation of a new data port for the association with the AP. The IHV Extensions DLL is passed the current state of the data port through the *pPortState* parameter of the *Dot11ExtIhvPerformPostAssociate* function. For more information about the port state parameter, see **DOT11_PORT_STATE**.
- The parameters of the association between the wireless LAN (WLAN) adapter and the AP. The IHV Extensions DLL is passed the association parameters through the *pDot11AssocParams* parameter of the *Dot11ExtIhvPerformPostAssociate* function. For more information about the association parameters, see **DOT11_ASSOCIATION_COMPLETION_PARAMETERS**.

When *Dot11ExtIhvPerformPostAssociate* is called, the IHV Extensions DLL initiates a post-association operation with the AP to authenticate the data port. Through this operation, the IHV Extensions DLL can do the following:

- Allocate any resources needed for the new data port.
- Perform proprietary security processing on the data port for the association. The IHV Extensions DLL can determine the current state of the data port from *pPortState* parameter of the *Dot11ExtIhvPerformPostAssociate* function.

- Call the **Dot11ExtSendUIRequest** function to request the IHV UI Extensions DLL to prompt the user for security parameters, such as the user's credentials.

- Authenticate with the AP using the authentication algorithm enabled through **Dot11ExtSetAuthAlgorithm**. The IHV Extensions DLL calls **Dot11ExtSetAuthAlgorithm** during the pre-association operation. For more information about this operation, see Pre-Association Operations.

- Send security packets to the AP through calls to the **Dot11ExtSendPacket** function.

  When the security packet has been sent, the operating notifies the IHV Extensions DLL through a call to the *Dot11ExtIhvSendPacketCompletion* function.

  For more information about sending security packets, see Send Operations.

- Receive security packets from the AP. The operating system calls the *Dot11ExtIhvReceivePacket* function for each security packet received by the WLAN adapter.

  Each received security packet is serialized and indicated in the order they were received from the WLAN adapter. The operating system only calls the *Dot11ExtIhvReceivePacket* function to indicate received security packets that match an entry in the list of IEEE EtherTypes, which were specified by the IHV Extensions DLL through a call to the **Dot11ExtSetEtherTypeHandling** function.

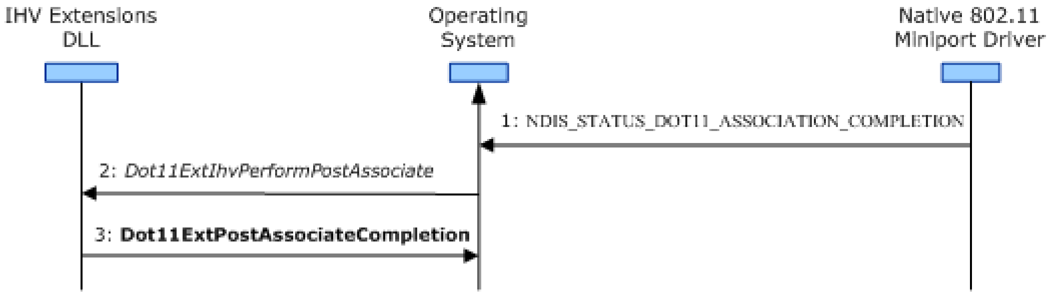
  For more information about receiving security packets, see Receive Operations.

- Configure the WLAN adapter with the cipher keys that are derived through the authentication algorithm. The following IHV Extensibility functions can be called to download the cipher keys to the WLAN adapter.
  - **Dot11ExtSetDefaultKey**
  - **Dot11ExtSetDefaultKeyId**
  - **Dot11ExtSetKeyMappingKey**

- Configure the WLAN adapter to exclude unencrypted packets through a call to the **Dot11ExtSetExcludeUnencrypted** IHV Extensibility function.

After the data port has been authenticated, the IHV Extensions DLL must call **Dot11ExtPostAssociateCompletion** to complete the post-association operation.

The following figure shows the steps involved during the post-association operation.



IHV Extensions DLL
Operating System
Native 802.11 Miniport Driver
1: NDIS_STATUS_DOT11_ASSOCIATION_COMPLETION
2: Dot11ExtIhvPerformPostAssociate
3: Dot11ExtPostAssociateCompletion

The IHV Extensions DLL must follow these guidelines when performing the post-association operation.

- The IHV Extensions DLL must call **Dot11ExtPostAssociateCompletion** asynchronously from the call to *Dot11ExtIhvPerformPostAssociate*.

- After completing the post-association operation, the IHV Extensions DLL can call **Dot11ExtPostAssociateCompletion** whenever the authentication status of the data port changes.

- If the *Dot11ExtIhvAdapterReset* function is called, the IHV Extensions DLL must cancel all pending post-association operations by calling **Dot11ExtPostAssociateCompletion**. For more information about the reset operation, see 802.11 WLAN Adapter Reset.

- If the *Dot11ExtIhvDeinitAdapter* function is called, the IHV Extensions DLL must cancel all pending post-association operations internally. However, it must not call any of the IHV Extensibility functions that can be called only after adapter initialization, including **Dot11ExtPostAssociateCompletion**. For more information about the IHV Extensibility functions, see Native 802.11 IHV Extensibility Functions.

Stopping a Post-Association Operation

Article • 12/15/2021

The operating system terminates the post-association operation by calling the *Dot11ExtIhvStopPostAssociate* IHV Handler function whenever one of the following occurs.

- The wireless LAN (WLAN) adapter completes a disassociation operation with the AP. In this situation, the Native 802.11 station, which manages the adapter, makes a media-specific NDIS_STATUS_DOT11_DISASSOCIATION indication. For more information about the disassociation operation, see Disassociation Operations.

- The WLAN adapter is disabled or removed. In this situation, the operating system calls the *Dot11ExtIhvStopPostAssociate* function before it calls the *Dot11ExtIhvDeinitAdapter* function.

The operating system calls the *Dot11ExtIhvStopPostAssociate* function to notify the IHV Extensions DLL that the data port created for the association with an AP is down. The operating system calls this function regardless of whether the DLL has completed the post-association operation through a call to **Dot11ExtPostAssociateCompletion**.

When *Dot11ExtIhvStopPostAssociate* is called, the IHV Extensions must release all of the resources allocated for the data port. If the post-association operation was not completed with a call to **Dot11ExtPostAssociateCompletion**, the IHV Extensions DLL must cancel the operation internally but must not call **Dot11ExtPostAssociateCompletion**.

Interface to the Native 802.11 802.1X Module

Article • 12/15/2021

After the operating system receives an NDIS_STATUS_DOT11_ASSOCIATION_COMPLETION indication from the Native 802.11 miniport driver, it calls the *Dot11ExtIhvPerformPostAssociate* function to initiate a post-association operation by the IHV Extensions DLL.

While it performs the post-association operation or after the operation has completed, the IHV Extensions DLL can use the extensible authentication protocol (EAP) algorithms that are supported by the operating system to authenticate the user with the access point (AP). In this situation, the IHV Extensions DLL interfaces with the 802.1X module of the Native 802.11 framework for the processing of EAP packets that are sent by the AP in the EAP over LAN (EAPOL) format.

For more information about the EAPOL format, refer to Clause 7 of the IEEE 802.1X-2001 standard.

For more information about the 802.1X module and the Native 802.11 framework, see Native 802.11 Software Architecture.

When interfacing the 802.1X module for user authentication, the IHV Extensions DLL must follow these guidelines:

- For Windows Vista, the IHV Extensions DLL can initiate 802.1X authentication operations through the 802.1X module only for infrastructure basic service set (BSS) network connections.

- The IHV Extensions DLL must register with the operating system to receive EAPOL packets. In this situation, the DLL must call the **Dot11ExtSetEtherTypeHandling** function and add the IEEE EAPOL EtherType (0x888E) to the list of registered EtherTypes that are passed in through the *pusRegistration* parameter. After the EtherType is registered, the operating system forwards received EAPOL packets to the IHV Extensions DLL through calls to the *Dot11ExtIhvReceivePacket* IHV Handler function.

  For more information about registering EtherTypes, see IEEE EtherType Handling.

- While it is performing the post-association operation, the IHV Extensions DLL initiates the 802.1X authentication operation by calling the **Dot11ExtStartOneX** function. When this function is called, the operating system does the following:
  - Display the properties page for the configuration of the 802.1X authentication. This information includes the EAP algorithm used for the authentication.
  - Prompt the user for credentials.
  - Send an EAPOL-Start packet to the AP to initiate the 802.1X authentication.

  The IHV Extensions DLL can call **Dot11ExtStartOneX** either within the call to *Dot11ExtIhvPerformPostAssociate* or after the function call returns.

- The IHV Extensions DLL can call the **Dot11ExtStartOneX** function only after the Native 802.11 miniport driver has completed an association operation with the AP. In this situation, the IHV Extensions DLL must not call the **Dot11ExtStartOneX** function under any of the following conditions:
  - Before the operating system calls *Dot11ExtIhvPerformPostAssociate*. The operating system calls this function after the miniport driver has successfully completed an association operation. For more information about this operation, see Association Operations.
  - After the operating system calls *Dot11ExtIhvStopPostAssociate*. The operating system calls this function after the miniport driver has completed a disassociation operation with the AP. For more information about this operation, see Disassociation Operations.
  - After the operating system calls *Dot11ExtIhvAdapterReset*. The operating system calls this function after the miniport driver has completed a disconnection operation with the basic service set (BSS) network. For more information about this operation, see Disconnection Operations.

- While the 802.1X authentication operation is in progress, the IHV Extensions DLL can cancel the operation by calling **Dot11ExtStopOneX**.

- While the 802.1X authentication operation is in progress, the IHV Extensions DLL must call **Dot11ExtProcessOneXPacket** to forward EAPOL packets to the operating system for processing. **Note** The IHV Extensions DLL is responsible for processing EAPOL-Key packets received from the AP. The DLL must not pass these packets to the operating system through calls to **Dot11ExtProcessOneXPacket**.

- When the 802.1X authentication operation completes, the operating system calls the *Dot11ExtIhvOneXIndicateResult* IHV Handler function. After this function is called, the IHV Extensions DLL is responsible for processing all EAPOL packets received from the AP, such as the EAPOL-Key packets used for derivation of the cipher keys.

- If the 802.1X authentication operation completed successfully, the operating system passes the MPPE-Send-Key value to the DOT11_MSONEX_RESULT_PARAMS structure pointed to by the *pDot11MsOneXResultParams* parameter of *Dot11ExtIhvOneXIndicateResult*. The MPPE-Send-Key value pointed to by the **pbMPPESendKey** member of DOT11_MSONEX_RESULT_PARAMS is derived through the authentication process and is used by the IHV Extensions DLL when sending EAPOL-Key packets to the AP. This key is encrypted and should be decrypted by calling the **CryptUnprotectData** function that is documented in the Windows SDK.

- The algorithm that is used to derive the cipher keys is dependent upon the implementation of the independent hardware vendor (IHV). The IHV Extensions DLL can support standard key derivation algorithms, such as the algorithm defined in Clause 8.5 of the IEEE 802.11i-2004 standard, as well as it can support a proprietary key derivation algorithm.

- After it derives the keys, the IHV Extensions DLL can call the following functions to download the cipher keys to the Native 802.11 miniport driver, which manages the wireless LAN (WLAN) adapter.

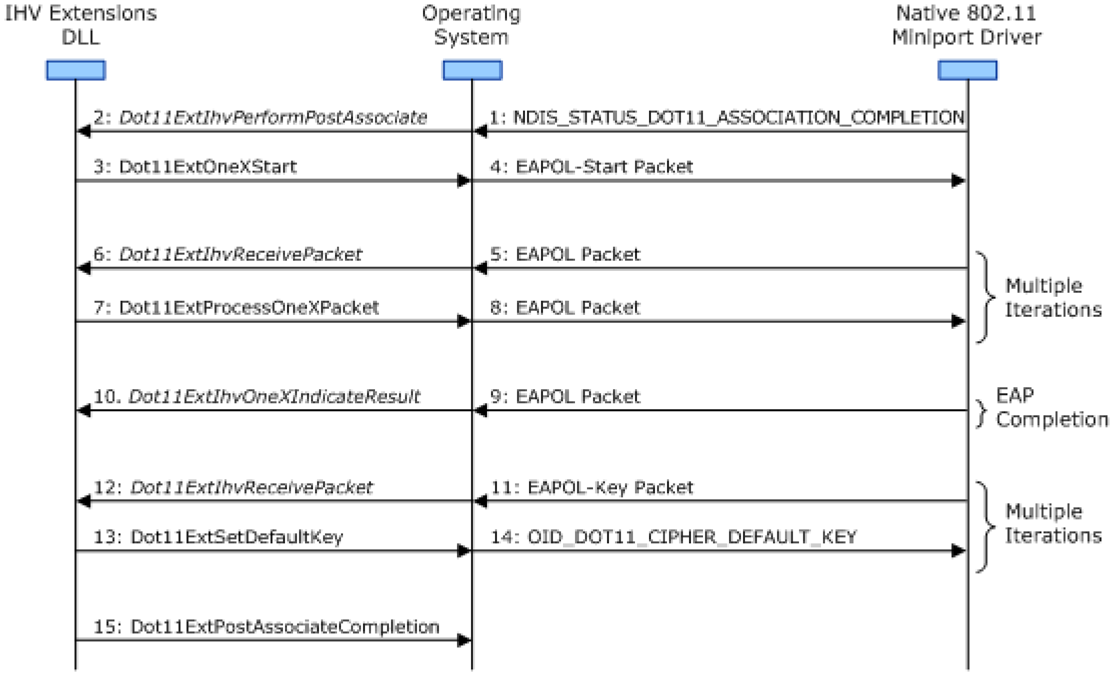
  - Dot11ExtSetDefaultKey

  - Dot11ExtSetDefaultKeyId

  - Dot11ExtSetKeyMappingKey

- The IHV Extensions DLL completes the post-association operation by calling the Dot11ExtPostAssociateCompletion function. After the post-association operation completes, the IHV Extensions DLL can initiate another 802.1X authentication operation if the DLL determines that the user must be reauthenticated.

The following figure shows the sequence of events when the IHV Extensions DLL initiates an 802.1X authentication operation during a post-association operation.



IHV Extensions DLL
Operating System
Native 802.11 Miniport Driver
1: NDIS_STATUS_DOT11_ASSOCIATION_COMPLETION
2: *Dot11ExtIhvPerformPostAssociate*
3: Dot11ExtOneXStart

15: Dot11ExtPostAssociateCompletion

Native 802.11 IHV extension send and receive operations

Article • 12/15/2021

This section describes the guidelines the IHV Extensions DLL follows when sending or receiving packets and contains the following topics:

IEEE EtherType Handling

Send Operations

Receive Operations

IEEE EtherType Handling

Article • 12/15/2021

The IHV Extensions DLL can specify a list of IEEE EtherTypes for special handling of packets received by the wireless LAN (WLAN) adapter. The following types of EtherType handling can be specified.

Privacy Exemptions
The IHV Extensions DLL can specify packet decryption exemptions for received packets. For example, the DLL can specify that a packet with a specified EtherType is allowed to be received unencrypted even if a matching cipher key is configured on the WLAN adapter.

EtherType Registration
The IHV Extensions DLL can register the EtherTypes that it will process and consume. The operating system forwards packets that match a registered EtherType to the DLL through calls to the *Dot11ExtIhvReceivePacket* function.

The IHV Extensions DLL specifies EtherType handling through a call to the **Dot11ExtSetEtherTypeHandling** function. When calling this function, the IHV Extensions DLL must follow these guidelines.

- The IHV Extensions DLL can only call **Dot11ExtSetEtherTypeHandling** any time prior to completing a pre-association operation. For more information about this operation, see Pre-Association Operations.

- The IHV Extensions DLL specifies its list of privacy exemptions through an array of zero or more **DOT11_PRIVACY_EXEMPTION** structures. If the IHV Extensions DLL does not call **Dot11ExtSetEtherTypeHandling**, the operating system defaults to an empty list of privacy exemptions for any 802.11 association with an access point (AP). **Note** For Windows Vista, the IHV Extensions DLL supports only infrastructure basic service set (BSS) networks.

- The IHV Extensions DLL registers a list of zero or more EtherTypes that it will receive. Typically, the DLL registers the EtherTypes for the security packets it processes during the post-association operation. For more information about this operation, see Post-Association Operations.

If the IHV Extensions DLL does not call **Dot11ExtSetEtherTypeHandling**, the operating system defaults to an empty list of registered EtherTypes for any 802.11 association with an AP.

- After the IHV Extensions DLL completes the pre-association operation by calling **Dot11ExtPreAssociateCompletion**, the list of privacy exemptions and EtherType registrations specified through a call to **Dot11ExtSetEtherTypeHandling** is applied to every 802.11 association made by the WLAN adapter while connected to the basic service set (BSS) network.

- The operating system clears the list of privacy exemptions and EtherType registrations before it calls *Dot11ExtIhvAdapterReset*.

Send Operations

Article • 12/15/2021

When performing a post-association operation, initiated through a call to *Dot11ExtIhvPerformPostAssociate*, the IHV Extensions DLL can send packets through the wireless LAN (WLAN) adapter. For more information about the post-association operation, see Post-Association Operations.

Typically, the DLL sends security packets to an access point (AP) for data port authentication by using the algorithm enabled through **Dot11ExtSetAuthAlgorithm**. The IHV Extensions DLL calls **Dot11ExtSetAuthAlgorithm** during the pre-association operation. For more information about this operation, see Pre-Association Operations.

Note For Windows Vista, the IHV Extensions DLL supports only infrastructure basic service set (BSS) networks.

When sending packets, the IHV Extensions DLL must follow these guidelines.

- The IHV Extensions DLL must allocate the memory for a complete 802.11 data packet, including 802.11 media access control (MAC) header, LLC encapsulation (if necessary), and payload data.

  The following table describes which fields and subfields within the 802.11 MAC header are set by the IHV Extensions DLL or WLAN adapter.

Field name	Subfield name	Set by IHV Extension DLL	Set by WLAN adapter
Frame Control	Protocol Version	X	
Frame Control	Type	X	
Frame Control	Subtype	X	
Frame Control	To DS	X	
Frame Control	From DS	X	
Frame Control	More Fragments		X
Frame Control	Retry		X

Field name	Subfield name	Set by IHV Extension DLL	Set by WLAN adapter
Frame Control	Pwr Mgt		X
Frame Control	More Data		X
Frame Control	Protected Frame		X
Frame Control	Order	X	
Duration/ID			X
Address 1		X	
Address 2		X	
Address 3		X	
Sequence Control	Fragment Number		X
Sequence Control	Sequence Number		X

- The IHV Extensions DLL calls the **Dot11ExtSendPacket** function to send the packet through the wireless LAN (WLAN) adapter. The DLL passes a unique handle value, which identifies the packet, to the function's *hSendCompletion* parameter. Typically, the DLL passes the address of the allocated buffer that contains the packet to the *hSendCompletion* parameter. **Note** Only unicast packets can be sent through calls to the **Dot11ExtSendPacket** function.

- When the WLAN adapter has sent the packet, the operating system calls the *Dot11ExtIhvSendPacketCompletion* function. The operating system passes the packet's handle value to the *hSendCompletion* parameter of the function. This handle value will be the same value used by the IHV Extensions DLL in its call to **Dot11ExtSendPacket**.

  When *Dot11ExtIhvSendPacketCompletion* is called, the IHV Extensions DLL must release the memory it allocated for the packet.

  Note The IHV Extensions DLL must not free the resources allocated for a packet sent through **Dot11ExtSendPacket** until the corresponding call to *Dot11ExtIhvSendPacketCompletion* is made.

Receive Operations

Article • 12/15/2021

When performing a post-association operation, initiated through a call to *Dot11ExtIhvPerformPostAssociate*, the operating system calls the *Dot11ExtIhvReceivePacket* function to forward packets to the HV Extensions DLL received through the wireless LAN (WLAN) adapter. For more information about the post-association operation, see Post-Association Operations.

In order to receive packets, the IHV Extensions DLL must call **Dot11ExtSetEtherTypeHandling** to register a list of one or more IEEE EtherTypes. When a packet is received with an EtherType that matches an entry in this list, the operating system calls the *Dot11ExtIhvReceivePacket* function and passes the packet buffer through the function's *pvInBuffer* parameter.

Note The IHV Extensions DLL must call **Dot11ExtSetEtherTypeHandling** before the DLL completes a pre-association operation. For more information about this operation, see Pre-Association Operations.

When *Dot11ExtIhvReceivePacket* is called, the *pvInBuffer* parameter points to a buffer allocated by the operating system that contains the entire 802.11 packet, including media access control (MAC) header, LLC encapsulation (if necessary), and payload data.

The IHV Extensions DLL can send a response to the received packet from within the call to *Dot11ExtIhvReceivePacket*. In this situation, the DLL must follow the guidelines described in Send Operations.

Notification Operations

Article • 12/15/2021

This section describes the types of notifications the IHV Extensions DLL sends or receives and contains the following topics:

Sending Notifications

Receiving Notifications

Sending Notifications

Article • 12/06/2022

The IHV Extensions DLL calls the Dot11ExtSendNotification function to send notifications to any service or application that has registered for the notification. In order to receive the notification, the service or application must register with the Auto Configuration Manager (ACM) by calling the WlanRegisterNotification function.

Note The service or application must register for notifications with a source value of L2_NOTIFICATION_SOURCE_WLAN_IHV in order to receive notifications through calls to the Dot11ExtSendNotification function.

When calling Dot11ExtSendNotification, the IHV Extensions DLL passes a pointer to a L2_NOTIFICATION_DATA structure to the *pNotificationData* parameter. The L2_NOTIFICATION_DATA defines the type of the notification and can provide additional data about the notification to the IHV Extensions DLL.

Receiving Notifications

Article • 12/15/2021

The operating system forwards IHV-specific indications from the Native 802.11 miniport driver by calling the *Dot11ExtIhvReceiveIndication* function. For more information about how the driver makes this type of indication, see IHV-Specific Indications.

When the *Dot11ExtIhvReceiveIndication* function is called, the *pvBuffer* parameter is passed a pointer to a buffer that contains data in a format defined by the IHV.

Virtual Station

Article • 12/15/2021

Beginning with NDIS 6.20 (Windows 7), the operating system provides a virtual station (VSTA) that can interact with the 802.11 miniport driver.

An independent hardware vendor (IHV) uses VSTA functionality through the IHV Extensibility framework rather than through Win32 application programming interfaces (APIs).

The creation of the virtual station is initiated when the IHV Extensions DLL calls the **Dot11ExtRequestVirtualStation** function. The operating system creates only one virtual station on the computer at a time, and only if an IHV Extensions DLL issues a **Dot11ExtRequestVirtualStation** request.

The operating system calls the *Dot11ExtIhvInitVirtualStation* function to initialize the IHV Extensions DLL for virtual station operations. This call also initializes the user-mode API interface between the operating system and the DLL.

Note To ensure that a virtual station is created in a consistent fashion, a computer should have only one installation of the IHV Extensions DLL that attempts to use Virtual Station functionality. Even if more than one DLL is installed, only one virtual station can be created. The operating system cannot guarantee which DLL will have access to a virtual station after the computer is restarted. Note that if a virtual station already has been created at the request of one DLL and a second DLL then calls **Dot11ExtRequestVirtualStation**, a success code might be returned but a second virtual station will not be created. An IHV Extensions DLL should set a two-minute timer after it calls the **Dot11ExtRequestVirtualStation** function. If the timer expires before the virtual station adapter arrival event, the DLL should assume that the virtual station was not created.

Extensible AP/Virtual Station Interactions

If your driver implements virtual station functionality but cannot sustain both Extensible Access Point (ExtAP) and virtual station connections at the same time on different ports, the driver should perform the following actions.

- Inform the operating system whether a port that is being used for ExtAP can or cannot sustain functionality at all times. In particular, the driver should issue the following status indications on the ExtAP port, using the appropriate status code (**NDIS_STATUS_INDICATION**->**StatusCode**) and reason code:

  NDIS_STATUS_DOT11_STOP_AP
  Indicates that AP functionality cannot be sustained on the ExtAP port. In this case, set **DOT11_STOP_AP_PARAMETERS**-> **ulReason** to a value of DOT11_STOP_AP_REASON_AP_ACTIVE. Issue this status indication in the following situations:
  - Before the virtual station port begins to use the shared resource that would block simultaneous virtual station and ExtAP connections
  - If the ExtAP port transitions to the ExtAP INIT state, and virtual station resource use would prevent successful initialization of the ExtAP port.

  NDIS_STATUS_DOT11_CAN_SUSTAIN_AP
  Indicates that the virtual station port is disconnected, or that use of a virtual station resource will not prevent successful transition of the port to the ExtAP INIT state.

- While connecting to a virtual station port, call the **Dot11ExtSetVirtualStationAPProperties** function to provide information about the AP implementation that is hosted by the virtual station connection.

- Fail the virtual station port connections if the ExtAP port is running in the OP state and one of the following situations occurs:
  - One or more clients is on the ExtAP port.
  - The virtual station attempts to start a connection that duplicates Wireless Hosted Network settings.

Native 802.11 IHV UI Extensions DLL Overview

Article • 12/15/2021

If the independent hardware vendor (IHV) provides a Native 802.11 IHV Extensions DLL, the IHV can optionally provide a Native 802.11 IHV UI Extensions DLL. Through this DLL, the IHV can do the following:

- Extend the Microsoft Network Configuration user interface (UI) properties, which are used for wireless connection and security configuration settings. In this situation, the Native 802.11 IHV UI Extensions DLL can do the following:
  - Add custom display elements to the standard Microsoft 802.11 properties. For example, the Native 802.11 IHV UI Extensions DLL can add items to a list to provide the end user with selections for proprietary security options.
  - Launch a custom UI that you can use to configure proprietary connection and security settings.

  For more information about extending Microsoft 802.11 properties, see Extending 801.11 Properties.

- Launch a custom UI at the request of the Native 802.11 IHV Extensions DLL. Depending on the current state of the underlying Native 802.11 miniport driver, the operating system displays the UI as either of the following:

  - A set of wizard pages within the flow of the operating system's 802.11 UI. For example, if the Native 802.11 IHV Extensions DLL requires user credentials during a wireless LAN (WLAN) connection operation, the operating system displays the custom UI pages provided by the Native 802.11 UI Extensions DLL as part of the standard UI flow.

    A stand-alone UI launched from a balloon notification. For example, if the Native 802.11 Extensions DLL determines that the connection or authentication state on the WLAN connection has changes, the DLL can request that the Native 802.11 UI Extensions DLL display a balloon notification to alert the end user.

  For more information about launching a UI that results from requests from the Native 802.11 Extensions DLL, see Handling UI Requests from the Native 802.11 IHV Extensions DLL.

For more information about the Native 802.11 IHV Extensions DLL, see Native 802.11 IHV Extensions DLL.

For more information about the Microsoft Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Native 802.11 IHV UI Extensions COM Interfaces

Article • 12/15/2021

The Native 802.11 IHV UI Extensions DLL implements one or more of the following COM interfaces:

IDot11ExtUI
Through the **IDot11ExtUI** COM interface, the operating system's Native 802.11 Network Configuration UI can interact with the Native 802.11 IHV UI Extensions DLL. For example, this COM interface provides the methods used by the Native 802.11 Network Configuration UI to query the DLL for the **IDot11ExtUIProperty** COM interfaces that are used to extend the operating system's 802.11 connection and security properties.

The Native 802.11 IHV UI Extensions DLL must provide an implementation of the **IDot11ExtUI** COM interface.

For more information about this COM interface, see IDot11ExtUI COM Interface.

IDot11ExtUIProperty
Through the **IDot11ExtUIProperty** COM interface, the Native 802.11 IHV UI Extensions DLL can extend the connection and security properties that are displayed by the Native 802.11 Network Configuration UI.

The **IDot11ExtUIProperty** COM interface is optional and is only required if the Native 802.11 IHV UI Extensions DLL supports extensions to the operating system's 802.11 connection and security properties.

The Native 802.11 IHV UI Extensions DLL can provide one or more implementations of the **IDot11ExtUIProperty** COM interface, with each implementation representing an IHV-defined extension to a Native 802.11 property. The DLL can provide one or more property extensions for security settings. For Windows Vista, the DLL can add no more than one property extension for connection settings.

For more information about this COM interface, see IDot11ExtUIProperty COM Interface.

IWizardExtension
The Native 802.11 IHV UI Extensions DLL can provide one or more implementations of the **IWizardExtension** COM interface. Each implementation supports the display of one or more custom UI pages. These UI pages are displayed through one of the following:

- An external request made by the Native 802.11 IHV Extensions DLL. For more information about this process, see Requesting the Display of a Custom UI.

- A query made by the operating system to determine whether the Native 802.11 IHV Extensions DLL has a custom UI to display. For more information about this process, see Querying for the Display of a Custom UI.

- An internal request made by a component of the Native 802.11 IHV UI Extensions DLL.

For more information about the **IWizardExtension** COM interface, see IWizardExtension COM Interface.

For more information about the Native 802.11 Network Configuration UI component, see Native 802.11 Software Architecture.

Extending the Properties for Wireless Network Profiles

Article • 12/15/2021

The end user creates or edits a wireless network connection profile through the Native 802.11 Network Configuration user interface (UI). For more information about this UI, see Native 802.11 Software Architecture.

The independent hardware vendor (IHV) can extend the Network Configuration UI to support proprietary connection and security profile settings through a Native 802.11 UI Extensions DLL. The DLL can extend the following tabs that are displayed in the Network Configuration UI.

Connection tab
This tab displays the UI for the connection settings of a wireless LAN (WLAN) network.

The Native 802.11 IHV UI Extensions DLL can extend this UI by following the procedure described in Extending Wireless Connection Property Pages.

Note For Windows Vista, the Native 802.11 UI Extensions DLL can only support one extension to the **Connection** tab.

Security tab
This tab displays the UI for the security settings of a wireless LAN (WLAN) network.

The Native 802.11 IHV UI Extensions DLL can extend this UI by adding display elements for proprietary security settings. For more information about this process, see Extending Wireless Security Property Pages.

The Native 802.11 IHV UI Extensions DLL can also extend the Microsoft 802.1X settings on the **Security** tab. For more information about this process, see Extending Microsoft 802.1X Security Settings.

Note For Windows Vista, the Native 802.11 IHV UI Extensions DLL can only extend the properties of connection and security profiles for infrastructure wireless networks.

Extending Wireless Connection Properties

Article • 12/15/2021

This topic describes how a Native 802.11 IHV UI Extensions DLL extends the properties on the **Connection** tab that are displayed through the Network Configuration user interface (UI). In this situation, the Native 802.11 IHV UI Extensions DLL adds properties to the **Connection** tab for proprietary connection settings.

For more information about the Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Before it displays the **Connection** tab, the operating system does the following:

1. Queries the Native 802.11 IHV UI Extensions DLL for its connection properties through a call to the **IDot11ExtUI::GetDot11ExtUIProperties** method. The operating system passes a value of **DOT11_EXT_UI_CONNECTION** to the method's *ExtType* parameter.

   If the Native 802.11 IHV UI Extension DLL supports a property of type **DOT11_EXT_UI_CONNECTION**, the DLL returns (through the method's *ppDot11ExtUIProperty* parameter) the address of the IDot11ExtUIProperty COM interface, which implements the connection property extension. For more information about the COM interfaces that are used to extend connection properties, see Native 802.11 IHV UI Extensions COM Interfaces.

   Note For Windows Vista, the Native 802.11 IHV UI Extensions DLL must not return more than one IDot11ExtUI COM Interface for a connection property extension.

2. If the Native 802.11 IHV UI Extensions DLL supports a connection property, the operating system queries the friendly name of the property extension by calling the extension's **IDot11ExtUIProperty::GetDot11ExtUIPropertyFriendlyName** method. The operating system inserts the friendly name within the text "Enable *xxx* connection settings," where "*xxx*" is the friendly name of the property extension. The operating system displays this text along with a check box on the **Connection** tab.

3. Queries the extension to determine whether it has a custom UI property that can be displayed. The operating system does this by calling the extension's IDot11ExtUIProperty::Dot11ExtUIPropertyHasConfigurationUI method. If the connection property extension supports a custom UI property, the operating system adds a **Configure** button below the check box for the property.

If the selected proprietary connection setting supports a configuration UI and the end user clicks the **Configure** button in the**Connection** tab, the operating system calls the connection property extension's IDot11ExtUIProperty::DisplayDot11ExtUIProperty method to launch the custom UI. The operating system passes the current profile data for the extension through the method's *bstrIHVProfile* argument.

The profile data is formatted as an XML fragment bounded by the <IHV> </IHV> XML tags. The XML data within these tags is specific to the IHV's implementation and is opaque to the operating system. For more information about the format of the Native 802.11 profile data, refer to the documentation within the Microsoft Windows SDK.

If the profile data is changed through the custom UI, the extension's IDot11ExtUIProperty::DisplayDot11ExtUIProperty method must do the following before returning:

- Allocate a string buffer for the modified profile data and return a pointer to the buffer through the method's *bstrModifiedIHVProfile* parameter. **Note** The extension's IDot11ExtUIProperty::DisplayDot11ExtUIProperty method must not modify the data referenced by the *bstrIHVProfile* argument.

- Set the *pbIsModified* argument to **TRUE**.

Extending Wireless Security Properties

Article • 12/15/2021

This topic describes how a Native 802.11 IHV UI Extensions DLL extends the properties of the **Security** tab that is displayed through the Network Configuration user interface (UI). In this situation, the Native 802.11 IHV UI Extensions DLL adds properties to the **Security** tab for proprietary security settings that are mutually exclusive from the Native 802.11 802.1X module.

The Native 802.11 IHV UI Extensions DLL can also extend the security and encryption methods that are supported by the Native 802.11 802.1X module. For more information about how the DLL does this, see Extending Microsoft 802.1X Security Settings.

For more information about the Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Before it displays the **Security** tab, the operating system does the following:

1. Queries the Native 802.11 IHV UI Extensions DLL for its security property extensions through a call to the **IDot11ExtUI::GetDot11ExtUIProperties** method. The operating system passes a value of **DOT11_EXT_UI_SECURITY** to the method's *ExtType* parameter.

   If the Native 802.11 IHV UI Extension DLL supports one or more properties of type **DOT11_EXT_UI_SECURITY**, the DLL returns (through the method's *ppDot11ExtUIProperty* parameter) a list of IDot11ExtUIProperty COM interfaces for the security property extensions that are supported by the DLL. For more information about the COM interfaces used to extend security properties, see Native 802.11 IHV UI Extensions COM Interfaces.

2. Queries the friendly name of the security extension by calling the extension's **IDot11ExtUIProperty::GetDot11ExtUIPropertyFriendlyName** method. The operating system adds the friendly name to the list of proprietary security settings at the bottom of the **Security** tab.

3. If the end user selects an item from this list, the operating system will call the **IDot11ExtUIProperty::Dot11ExtUIPropertyGetSelected** method of each security extension's IDot11ExtUIProperty COM interfaces. The first extension that returns with a value of **TRUE** for the method's *pfIsSelected* parameter is determined to be the selected extension. The selected entry in the list will then be highlighted.

4. Queries the selected setting's **IDot11ExtUIProperty::Dot11ExtUIPropertyHasConfigurationUI** method to determine whether it has a custom UI property page that can be displayed. If the method returns with the *fHasConfigurationUI* parameter set to **TRUE**, the operating system will add a **Configure** button next to the list of proprietary security settings.

If the selected proprietary security setting supports a configuration UI and the end user clicks the **Configure** button, the operating system calls the setting's **IDot11ExtUIProperty::DisplayDot11ExtUIProperty** method to launch the custom UI. The operating system passes the current profile data for the setting through the method's *bstrIHVProfile* argument.

The profile data is formatted as an XML fragment bounded by the <IHV> </IHV> XML tags. The XML data within these tags is specific to the IHV's implementation and is opaque to the operating system. For more information about the format of the Native 802.11 profile data, refer to the documentation within the Microsoft Windows SDK.

If the profile data is changed through the custom UI, the setting's **IDot11ExtUIProperty::DisplayDot11ExtUIProperty** method must do the following before returning:

- Allocate a string buffer for the modified profile data and return a pointer to the buffer through the method's *bstrModifiedIHVProfile* parameter. **Note** The setting's **IDot11ExtUIProperty::DisplayDot11ExtUIProperty** method must not modify the data that is referenced by the *bstrIHVProfile* argument.

- Set the *pbIsModified* argument to **TRUE**.

Extending Microsoft 802.1X Security Settings

Article • 12/15/2021

If the Native 802.11 IHV Extensions DLL supports extensions to the Native 802.11 802.1X module, the Native 802.11 IHV UI Extensions DLL can extend the Network Configuration user interface's (UI's) **Security** tab to allow user configuration of the 802.1X extensions. For more information about extending the Native 802.11 802.1X module, see Interface to the Native 802.11 802.1X Module.

This section describes how the Native 802.11 IHV UI Extensions DLL can extend the settings for the operating system's security and encryption methods supported by the Native 802.11 802.1X module. This section includes the following topics:

Extending the UI for Proprietary 802.1X Security Methods

Extending the UI for Standard 802.1X Security Methods

For more information about the Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Extending the UI for Proprietary 802.1X Security Methods

Article • 12/15/2021

If the Native 802.11 IHV Extensions DLL supports proprietary 802.1X-based security extensions, the Native 802.11 IHV UI Extensions DLL can extend the Network Configuration user interface's (UI's) **Security** tab to allow user configuration of the these extensions. For more information about extending the Native 802.11 802.1X module, see Interface to the Native 802.11 802.1X Module.

For more information about the Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Before it displays the **Security** tab, the operating system does the following:

1. Queries the Native 802.11 IHV UI Extensions DLL for its security property extensions through a call to the **IDot11ExtUI::GetDot11ExtUIProperties** method. The operating system passes a value of **DOT11_EXT_UI_KEYEXTENSION** to the method's *ExtType* parameter.

   Property extensions of type **DOT11_EXT_UI_KEYEXTENSION** do not provide security settings that are mutually exclusive to the standard Microsoft security settings. Instead, this type of security property extension provides IHV-defined 802.1X settings that are used together with the Microsoft 802.1X settings.

2. Queries the friendly name of the 802.1X security extension by calling the extension's **IDot11ExtUIProperty::GetDot11ExtUIPropertyFriendlyName** method.

3. Queries the extension's **IDot11ExtUIProperty::Dot11ExtUIPropertyIsStandardSecurity** method to determine whether the extension supports a security type extension. If the method sets the *fIsStandardSecurity* parameter to **FALSE**, the operating system will add the extension's friendly name to the **Security type** list on the **Security** tab.

4. When the end user selects an item from the **Security type** list, the operating system responds by calling the **IDot11ExtUIProperty::Dot11ExtUIPropertyGetSelected** method for each extension to match the selection of the end user. The first extension that returns a value of **TRUE** for the method's *pfIsSelected* parameter is determined to be the selected

extension. After this is confirmed, the operating system highlights the selection made by the end user.

5. Calls the selected property extension's **IDot11ExtUIProperty::Dot11ExtUIPropertyHasConfigurationUI** method to determine whether it has a custom UI property page that can be displayed. If the method returns a value of **TRUE** for the method's *fHasConfigurationUI* parameter, the operating system will display a **Configure** button next to the **Security type** list.

   If the end user clicks the **Configure** button, the operating system will call the selected property extension's **IDot11ExtUIProperty::DisplayDot11ExtUIProperty** method to display the custom configuration UI for the extension.

6. Calls the selected property extension's **IDot11ExtUIProperty::Dot11ExtUIPropertyGetDisplayInfo** method. Through this method, the Native 802.11 IHV UI Extensions DLL can return other property extensions to the **Security** tab of the Native 802.11 Network Configuration UI.

   The **IDot11ExtUIProperty::Dot11ExtUIPropertyGetDisplayInfo** method returns a list of the items that the selected property extension adds to the **Security** tab. Each entry in the list is formatted as a **DOT11_EXT_UI_PROPERTY_DISPLAY_INFO** structure.

   For Windows Vista, the Native 802.11 IHV UI Extensions DLL can only add items to the **Encryption** list on the **Security** tab. As a result, each item in the list of **DOT11_EXT_UI_PROPERTY_DISPLAY_INFO** structures must have a **DOT11_EXT_UI_DISPLAY_INFO_TYPE** of **DOT11_EXT_UI_DISPLAY_INFO_CIPHER** in order to be included in the **Encryption** list.

7. When the end user selects from the **Encryption** list, the operating system will call the selected property extension's **IDot11ExtUIProperty::Dot11ExtUIPropertySetDisplayInfo** method to process the profile data that is associated with the end user's selection.

Extending the UI for Standard 802.1X Security Methods

Article • 12/15/2021

If the Native 802.11 IHV Extensions DLL supports proprietary encryption extensions that can be used with the operating system's 802.1X security methods, the Native 802.11 IHV UI Extensions DLL can extend the Network Configuration user interface's (UI')s **Security** tab to allow user configuration of the these extensions. For more information about extending the Native 802.11 802.1X module, see Interface to the Native 802.11 802.1X Module.

For more information about the Network Configuration UI and other Native 802.11 components, see Native 802.11 Software Architecture.

Before it displays the **Security** tab,the operating system does the following:

1. Queries the Native 802.11 IHV UI Extensions DLL for its security property extensions through a call to the **IDot11ExtUI::GetDot11ExtUIProperties** method. The operating system passes a value of **DOT11_EXT_UI_KEYEXTENSION** to the method's *ExtType* parameter.

   Property extensions of type **DOT11_EXT_UI_KEYEXTENSION** do not provide security settings that are mutually exclusive to the standard Microsoft security settings. Instead, this type of security property extension provides IHV-defined 802.1X settings that are used together with the Microsoft 802.1X settings.

2. Queries the friendly name of the 802.1X security extension by calling the extension's **IDot11ExtUIProperty::GetDot11ExtUIPropertyFriendlyName** method.

3. Queries the extension's **IDot11ExtUIProperty::Dot11ExtUIPropertyIsStandardSecurity** method to determine whether the extension supports a security type extension. If the method sets the *fIsStandardSecurity* parameter to **TRUE**, the operating system will not add the extension's friendly name to the **Security type** list on the **Security** tab.

   In this situation, the extension adds functionality to the security settings that are supported by the operating system. The method specifies the type of security setting it extends through the *dot11ExtUISecurityType* parameter.

4. When the end user selects an item from the **Security type** list, the operating system responds by calling the IDot11ExtUIProperty::Dot11ExtUIPropertyGetSelected method for each extension to match the selection of the end user. The first extension that returns a value of **TRUE** for the method's *pfIsSelected* parameter is determined to be the selected extension. After this is confirmed, the operating system highlights the selection made by the end user.

5. When the end user selects an item for a standard security setting from the **Security type** list, the operating system calls the IDot11ExtUIProperty::Dot11ExtUIPropertyGetDisplayInfo method of the property extension that extends the security method. Through the **IDot11ExtUIProperty::Dot11ExtUIPropertyGetDisplayInfo** method, the Native 802.11 IHV UI Extensions DLL can return other items to be added to the **Security** tab of the Native 802.11 Network Configuration UI.

   The **IDot11ExtUIProperty::Dot11ExtUIPropertyGetDisplayInfo** method returns a list of the extended display properties that are supported by the property extension. Each item in the list is formatted as a DOT11_EXT_UI_PROPERTY_DISPLAY_INFO structure.

   For Windows Vista, the Native 802.11 IHV UI Extensions DLL can only add items to the **Encryption** list on the **Security** tab. As a result, each entry within the list of DOT11_EXT_UI_PROPERTY_DISPLAY_INFO structures must have a **DOT11_EXT_UI_DISPLAY_INFO_TYPE** of **DOT11_EXT_UI_DISPLAY_INFO_CIPHER** in order to be included in the **Encryption** list.

6. When the end user selects from the **Encryption** list, the operating system will call the property extension's IDot11ExtUIProperty::Dot11ExtUIPropertySetDisplayInfo method to process the profile data that is associated with the end user's selection.

Extending the Advanced Properties for Wireless Network Adapters

Article • 12/15/2021

In addition to extending the properties for wireless network profiles, the independent hardware vendor (IHV) can also extend the advanced properties for the configuration of the wireless LAN (WLAN) adapter. For more information, refer to the following topics:

Specifying Configuration Parameters for the Advanced Properties Page

Specifying Custom Property Pages for Network Adapters

Handling Requests for the Display of a Custom UI

Article • 12/15/2021

This section discusses how the Native 802.11 IHV UI Extensions DLL can display a custom user interface (UI) through one of the following:

- A request from the Native 802.11 IHV Extensions DLL. For example, the Native 802.11 IHV Extensions DLL might request a custom UI for user notification of a wireless LAN (WLAN) event.
- A query, made by the operating system, to determine whether the Native 802.11 IHV UI Extensions DLL has a custom UI that can be displayed.

This section has the following topics:

Requesting the Display of a Custom UI

Querying for the Display of a Custom UI

Displaying Custom UI Pages within a Balloon Notification

Displaying Custom UI Pages within the Network Connection Wizard

Accessing Profile and Context Data

For more information about the Native 802.11 IHV Extensions DLL, see Native 802.11 IHV Extensions DLL.

Requesting the Display of a Custom UI

Article • 12/15/2021

The Native 802.11 IHV Extensions DLL can request the display of a custom user interface (UI) through the Native 802.11 IHV UI Extensions DLL. For example, the IHV Extensions DLL could request that a custom UI be displayed to:

- Notify the end user at various stages during the wireless LAN (WLAN) association operation.
- Notify the end user when the WLAN adapter has disassociated for the WLAN network.
- Notify the end user with the results of the authentication to the WLAN network.

To launch a custom UI or display a notification, the Native 802.11 IHV Extensions DLL calls **Dot11ExtSendUIRequest** and passes a pointer to a **DOT11EXT_IHV_UI_REQUEST** structure through the *pIhvUIRequest* parameter of this function.

Through the **DOT11EXT_IHV_UI_REQUEST** structure, the Native 802.11 IHV Extensions DLL specifies the custom UI through the following data:

- The user session identifier (ID), which is used to identify a specific user context.
- A globally unique ID (GUID), which identifies the specific UI request.
- The class ID (CLSID) of **IWizardExtension** COM interface implemented within the Native 802.11 IHV UI Extensions DLL. The CLSID is used to request a specific custom UI supported by the DLL.

  For more information about the **IWizardExtension** COM interface, see IWizardExtension COM Interface.
- A buffer containing data in a proprietary format that is defined by the independent hardware vendor (IHV) and processed by the specified **IWizardExtension** COM interface. For example, the buffer could contain the default values that are displayed within the custom UI.

Depending upon the WLAN connection state for the user session ID, the custom UI request will be displayed as one of the following:

- If the adapter has connected to a WLAN network, the request will be displayed as a standalone UI launched through a clickable balloon notification. For more information about this process, see Displaying a Balloon Notification.

- If the adapter is in the process of connecting to a WLAN network, the request will be displayed as a set of wizard pages within the standard Network Connection UI. For more information about this process, see Displaying Custom UI Pages within the Network Connection Wizard.

Querying for the Display of a Custom UI

Article • 12/15/2021

The operating system can query the Native 802.11 IHV Extensions DLL to determine whether the DLL has a custom UI to display. The operating system queries the DLL whenever the wireless LAN (WLAN) adapter transitions to one of the following phases within the WLAN network connection process.

Pre-association
The connection phase before the IHV Extensions DLL initiates a pre-association operation. For more information about the pre-association operation, see Pre-Association Operations.

Post-association
The connection phase after the IHV Extensions DLL completes a post-association operation. For more information about the post-association operation, see Post-Association Operations.

The operating system calls the Native 802.11 IHV Extensions DLL's *Dot11ExtIhvQueryUIRequest* IHV Handler function to query whether a custom UI can be displayed. The operating system passes the current phase of the connection process through the *connectionPhase* parameter. If a custom UI must be displayed, the DLL returns a **DOT11EXT_IHV_UI_REQUEST** structure through the p *pIhvUIRequest* parameter.

Through the **DOT11EXT_IHV_UI_REQUEST** structure, the Native 802.11 IHV Extensions DLL specifies the custom UI through the following data.

- The user session identifier (ID), which is used to identify a specific user context.

- A globally unique ID (GUID), which identifies the specific UI request.

- The class ID (CLSID) of **IWizardExtension** COM interface that is implemented within the Native 802.11 IHV UI Extensions DLL. The CLSID is used to request a specific custom UI that is supported by the DLL.

  For more information about the **IWizardExtension** COM interface, see IWizardExtension COM Interface.

- A buffer that contains data in a proprietary format that is defined by the independent hardware vendor (IHV) and processed by the specified

IWizardExtension COM interface. For example, the buffer could contain the default values that are displayed within the custom UI.

The custom UI will be displayed as a set of wizard pages within the standard Network Connection UI. For more information about this process, see Displaying Custom UI Pages within the Network Connection Wizard.

Displaying Custom UI Pages within a Balloon Notification

Article • 12/15/2021

If the Native 802.11 IHV Extensions DLL calls **Dot11ExtSendUIRequest** to display a custom user interface (UI), the operating system will display the UI through a clickable balloon notification if the wireless LAN (WLAN) adapter has connected to a wireless network. In this situation, the request for the custom UI is displayed as a balloon notification:

- After the Native 802.11 IHV Extensions DLL calls **Dot11ExtPostAssociateCompletion** to successfully complete the post-association operation.
- Before the operating system calls the DLL's *Dot11ExtIhvAdapterReset* IHV Handler function to reset the WLAN connection.

For more information about how the Native 802.11 IHV Extensions DLL requests the display of a custom UI, see Requesting the Display of a Custom UI.

When processing a custom UI request as a balloon notification, the operating system does the following.

1. Calls the Native 802.11 IHV Extensions DLL's *Dot11ExtIhvIsUIRequestPending* IHV Handler function to determine whether a UI request is still pending. The operating system specifies the UI request using the globally unique identifier (GUID) passed to **Dot11ExtSendUIRequest** by the Native 802.11 IHV Extensions DLL.

2. If *Dot11ExtIhvIsUIRequestPending* returns **TRUE** for the specified UI request, the operating system will call the Native 802.11 IHV UI Extensions DLL's **IDot11ExtUI::GetDot11ExtUIBalloonText** method. Through this method, the DLL returns a string buffer that contains the localized text to be displayed within the balloon notification.

3. Displays the balloon notification that contains the localized text.

4. If the end user clicks the balloon notification, the operating system will launch the custom UI that is supported by the requested **IWizardExtension** COM interface. When it calls **Dot11ExtSendUIRequest**, the Native 802.11 IHV Extensions DLL

specifies the class identifier (CLSID) of the **IWizardExtension** implementation within the Native 802.11 IHV UI Extensions DLL.

When the operating system calls the **IWizardExtension::AddPages** method, the Native 802.11 IHV UI Extensions DLL returns an array of handles for PROPSHEETPAGE structures representing the custom UI pages.

For more information about the **IWizardExtension** COM interface, see IWizardExtension COM Interface. For more information about the PROPSHEETPAGE structure, refer to the documentation in the Microsoft Windows SDK.

5. Navigates through the UI pages as specified by the Native 802.11 IHV UI Extensions DLL through **IWizardSite** COM interface. For more information about this interface, see IWizardSite COM Interface.

While the custom UI is displayed, the Native 802.11 IHV UI Extensions DLL can read or write context-specific data through the IPropertyBag COM interface. For more information about this process, see Accessing Profile and Context Data. After the display of the custom UI has completed, the Native 802.11 IHV UI Extensions DLL can return the user-entered response data to the Native 802.11 IHV Extensions DLL by calling **WlanSendUIResponse** . The DLL passes in the GUID for the UI request as well as a pointer to a buffer that contains the response data.

After the Native 802.11 IHV UI Extensions DLLcalls **WlanSendUIResponse**, the operating system will call the Native 802.11 IHV Extension DLL's *Dot11ExtIhvProcessUIResponse* IHV Handler function to forward the response data for the custom UI.

For more information about the **WlanSendUIResponse** API, refer to the documentation in the Windows SDK.

Displaying Custom UI Pages within the Network Connection Wizard

Article • 12/15/2021

A custom user interface (UI) supported by the Native 802.11 IHV UI Extensions DLL can be displayed within the operating system's Network Connection Wizard when the request for UI is made through either:

- A call to **Dot11ExtSendUIRequest**, made by the Native 802.11 IHV Extensions DLL. For more information about this process, see Requesting the Display of a Custom UI.

- A call to the Native 802.11 IHV Extensions DLL's **Dot11ExtQueryUIRequest** IHV Handler function, made by the operating system. For more information about this process, see Querying for the Display of a Custom UI.

The operating system displays the custom UI within the Network Connection Wizard if the wireless LAN (WLAN) adapter is attempting to connect to a wireless network. In this situation, the request for the custom UI will be displayed as a balloon notification within the period:

- After the operating system calls the Native 802.11 IHV Extensions DLL's *Dot11ExtIhvPerformPreAssociate* IHV Handler function to initiate a pre-association operation with the wireless network.

- Before the Native 802.11 IHV Extensions DLL calls **Dot11ExtPostAssociateCompletion** to successfully complete the post-association operation.

When inserting the custom UI request within the Network Connection Wizard, the operating system does the following:

1. Calls the Native 802.11 IHV Extensions DLL's *Dot11ExtIhvIsUIRequestPending* IHV Handler function to determine whether a UI request is still pending. The operating system specifies the UI request using the globally unique identifier (GUID) that is passed to **Dot11ExtSendUIRequest** by the Native 802.11 IHV Extensions DLL.

2. If *Dot11ExtIhvIsUIRequestPending* returns **TRUE** for the specified UI request, the operating system will instantiate the requested **IWizardExtension** COM interface and bind it into the current UI flow of the Network Connection Wizard. When it

calls **Dot11ExtSendUIRequest**, the Native 802.11 IHV Extensions DLL specifies the class identifier (CLSID) of the **IWizardExtension** implementation within the Native 802.11 IHV UI Extensions DLL.

The operating system also calls the **IWizardExtension::AddPages** method, through which the Native 802.11 IHV UI Extensions DLL returns an array of handles for PROPSHEETPAGE structures representing the custom UI pages.

For more information about the **IWizardExtension** COM interface, see IWizardExtension COM Interface.

3. Navigates through the UI pages as controlled by the Native 802.11 IHV UI Extensions DLL through the **IWizardSite** COM interface. For more information about this interface, see IWizardSite COM Interface.

While the custom UI is displayed, the Native 802.11 IHV UI Extensions DLL can read or write context-specific data through the IPropertyBag COM interface. For more information about this process, see Accessing Profile and Context Data.

After the custom UI is displayed, the Native 802.11 IHV UI Extensions DLL can return the user-entered response data to the Native 802.11 IHV Extensions DLL by calling **WlanSendUIResponse**. The DLL passes in the GUID for the UI request as well as a pointer to a buffer containing the response data.

After the Native 802.11 IHV UI Extensions DLL calls **WlanSendUIResponse**, the operating system calls the Native 802.11 IHV Extension DLL's *Dot11ExtIhvProcessUIResponse* IHV Handler function to forward the response data for the custom UI.

For more information about the **WlanSendUIResponse** API, refer to the documentation in the Microsoft Windows SDK.

Accessing Profile and Context Data

Article • 12/15/2021

A custom user interface (UI) that is supported by the Native 802.11 IHV UI Extensions DLL can be displayed through either:

- A call to **Dot11ExtSendUIRequest** made by the Native 802.11 IHV Extensions DLL. For more information about this process, see Requesting the Display of a Custom UI.
- A call to the Native 802.11 IHV Extensions DLL's *Dot11ExtQueryUIRequest* IHV Handler function made by the operating system. For more information about this process, see Querying for the Display of a Custom UI.

Regardless of whether the UI request is displayed through either a balloon notification or the operating system's Network Connection Wizard, the Native 802.11 IHV UI Extensions DLL can access the following data:

Network connection profile data
If the custom UI is displayed within the Network Connection Wizard, the Native 802.11 IHV UI Extensions DLL can access the IHV-defined portion of the current network connection profile. This data is formatted as an XML fragment bounded by the <IHV> </IHV> XML tags. The XML data within these tags is specific to the IHV's implementation and is opaque to the operating system.

Access to the profile data is through the **Read** and **Write** methods of the IPropertyBag COM interface for a property named **IHV_PROFILE_DATA**.

Context data
The Native 802.11 IHV Extensions DLL specifies a custom UI through a **DOT11EXT_IHV_UI_REQUEST** structure, which is passed as an argument in both the **Dot11ExtSendUIRequest** and *Dot11ExtIhvQueryUIRequest* functions. Within the DOT11EXT_IHV_UI_REQUEST structure, the IHV can provide (through the **pvUIRequest** member) context data specific to the custom UI. Typically, the IHV formats this data with default settings for the custom UI.

Access to the profile data is through the **Read** and **Write** methods of the IPropertyBag COM interface for a property named **IHV_NOTIFICATION_DATA**.

The Native 802.11 IHV UI Extensions DLL accesses the IPropertyBag COM interface through the *IUnknown* pointer returned through the **IObjectWithSite::SetSite** method.

For more information, see IObjectWithSite.

As an alternative to the IPropertyBag COM interface, the Native 802.11 IHV UI Extensions DLL can access the **IHV_PROFILE_DATA** and **IHV_NOTIFICATION_DATA** properties through the GetProp Win32 function. In this situation, the DLL must use the handle of the parent window, as shown in the following example:

C++

```
LPWSTR lpszBuffer = (LPWSTR) GetProp(GetParent(hwndDlg),
L"IHV_PROFILE_DATA");
```

Wi-Fi Hotspot Offloading Overview

Article • 12/15/2021

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

Wi-Fi Hotspot Offloading enables Windows 10 Mobile to automatically identify and connect to local Wi-Fi networks designated as "hotspots." The Wi-Fi Hotspot Offload Framework enables mobile operators to ship phones preconfigured with customized hotspot plugins for Wi-Fi hotspot offloading.

In This Section

- Wi-Fi Hotspot Offloading Architecture
- Wi-Fi Hotspot Offloading Plugin
- Wi-Fi Discovery Service
- Wi-Fi Hotspot Offloading Reference

Wi-Fi Hotspot Offloading Architecture

Article • 12/15/2021

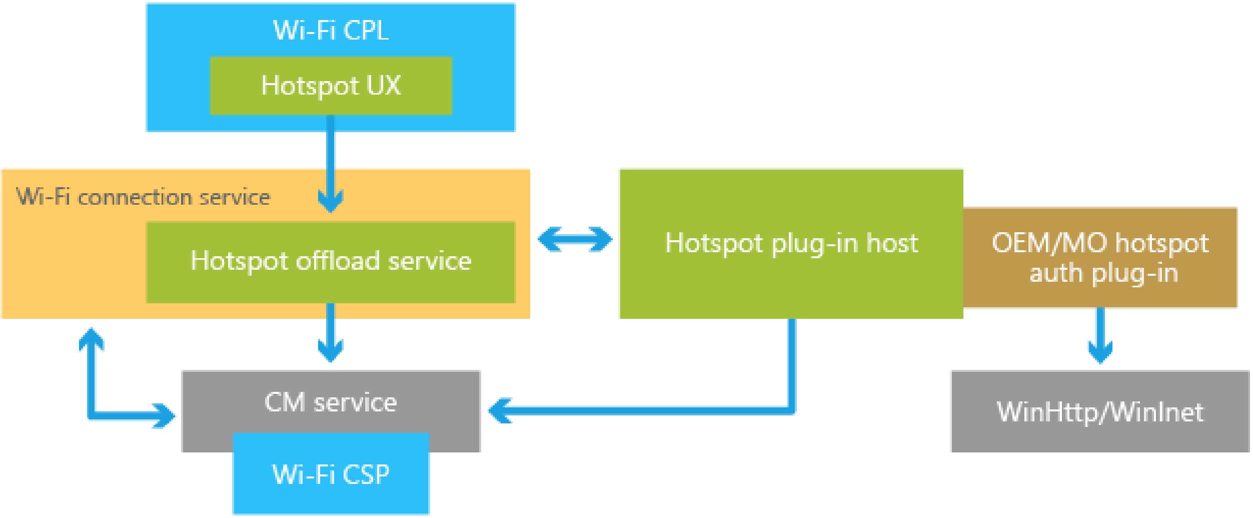
Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The following diagram shows the major components in the Wi-Fi Offload Framework.



Hotspot offload service

The hotspot offload service performs the following functions:

- Identifies Wi-Fi networks that are hotspot networks
- Oversees the creation and maintenance of connections to hotspot networks
- Monitors and responds to connection state changes for hotspot networks
- Monitors and responds to changes in user settings for enabling or disabling Wi-Fi hotspot offloading

The hotspot offload service relies on hotspot plugins created by mobile operators and/or OEMs to identify and authenticate their hotspot networks.

Hotspot plugin host

The hotspot plugin host is the interface between the hotspot offload service and the partner-implemented hotspot plugin. For example, queries to the hotspot plugin to identify hotspot networks from a list of networks are made through the hotspot plugin host. The plugin host also enables the hotspot plugin to, among other things, send and receive HTTP messages via the WinHTTP/WinInet API and send SMS alerts and notifications to the user.

The hotspot offload service is responsible for creating a hotspot plugin host for each hotspot plugin.

Hotspot plugin

The hotspot plugin performs the following functions:

- Identifies hotspot networks from a list of available networks
- Enables automatic connection to networks using EAP-SIM/AKA and HTTP-based authentication, as specified by the OEM or mobile operator
- Sends/receives HTTP messages via the WinHTTP/WinInet API
- Sends SMS notifications to the user
- Selects a bearer token for an HTTP request to send and receive messages over a cellular network

It also interacts directly with the following external components:

- WinInet/WinHTTP

Mobile operators and/or OEMs must implement and install their own hotspot plugins to enable Wi-Fi offloading. The installation package for the plugin includes the following:

- The plugin DLL
- Files containing connection-specific information such as a list of SSIDs, encrypted credentials, etc.
  - **Note:** These files are optional and are not expected in most plugins.
- Registry configuration

Hotspot user interface

The hotspot user interface is displayed in the Wi-Fi control panel. Through the user interface the user can:

- Enable/disable automatic Wi-Fi hotspot offloading.
- View connection status during automatic connection to a hotspot network.
- Manually connect to a hotspot network.
  - If hotspot offload functionality is enabled on the device, user-initiated connections to a network that the hotspot offload service has identified as a hotspot network will be handled as automatic connections to a Wi-Fi hotspot network. Otherwise, the manual connection will be handled as a standard Wi-Fi connection.
- Configure a normal Wi-Fi profile for connection to a hotspot network if the mobile operator hotspot connectivity has been disabled by the user.

The hotspot user interface is only displayed when at least one plugin is configured.

Example: Automatic connection to a hotspot network

The following is a very high-level description of the sequence of component interactions that occur during automatic connection to a hotspot network:

1. The Wi-Fi Connection Service sends to the Hotspot Offload Service a list of networks that are not connected.
2. For each entry in the list of networks, the Hotspot Offload Service queries the hotspot plugins (in the order the plugins were ranked) to determine if it is a hotspot network. The first plugin to identify the network is asked to authenticate that network at connection time.
3. When a hotspot plugin identifies a network as a hotspot network, it returns a priority value associated with that network, the authentication method to be used (whether it is HTTP-based, or EAP-SIM based, or requires no specific SIM) and, optionally, the network display mask. The priority value indicates the order in which a connection should be attempted. Connections to networks with lower priority values will be attempted before connections to networks with higher values.
4. The Hotspot Offload Service creates a Connection Manager profile for the selected network.
5. The Hotspot Offload Service profile may also configure an initial policy setting that will cause the Connection Manager to block applications from connecting to the network until authorized.
6. The Hotspot Offload Service marks the selected network as a hotspot network.

7. The Hotspot Offload Service calls the hotspot plugin, through the hotspot plugin host, to do any pre-connect processing if needed.
8. After the hotspot plugin has completed pre-connect processing, the Hotspot Offload Service waits for the Connection Manager to connect to the hotspot network and provide a connection-completion or failure notification.
9. On connection-completion, the Hotspot Offload Service sends a request to the hotspot plugin to perform any necessary post-connect actions, such as HTTPS exchange.
10. In the meantime, the Hotspot Offload Service does the following:

    - Starts a timer for completion of the post-connect activity (currently set to fire after 5 minutes)
    - Sets proper user interface display state

11. If the hotspot plugin indicates connection success, the Hotspot Offload service calls the Connection Manager to unblock the connection and notify applications.
12. If the post-connection request times out:

    - The Hotspot Offload Service resets the hotspot plugin's state.
    - If retries are not exhausted the hotspot offload service initiates an attempt to reconnect, otherwise it deletes the network's hotspot profile.

13. If the hotspot plugin indicates failure and retries are possible, the hotspot offload service initiates an attempt to reconnect, otherwise it deletes the network's hotspot profile.

Wi-Fi Hotspot Offloading Plugin

Article • 12/15/2021

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

To enable Wi-Fi offloading, create and install a hotspot plugin. This topic discusses a few of the issues to consider when developing a hotspot plugin. It also provides a general description of the plugin APIs to be implemented as part of the plugin package.

Planning the plugin

Before starting plugin development, make sure to address the following issues:

Supported authentication methods

Identify the authentication methods required by the networks that the plugin will support. The hotspot offload framework supports three classes of networks:

- Networks that use WISPr 1.0, or some variant, to authenticate the user and/or device over HTTP. These networks are represented by the following capability:
  - **HS_FLAG_CAPABILITY_NETWORK_AUTH_HTTP**
- Networks that use EAP-SIM/AKA/AKA' to authenticate the device. These networks are represented by the following capabilities:
  - **HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_SIM**
  - **HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_AKA**
  - **HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_AKA_PRIME**

  For EAP-based networks, the plugin can also specify a custom realm by using the **HS_FLAG_CAPABILITY_NETWORK_CUSTOM_REALM** capability.

- Networks that do not require any authentication or networks for which the plugin has an independent authentication mechanism that does not require any device credentials. These networks are represented by the following capability:
  - **HS_FLAG_CAPABILITY_NETWORK_AUTH_NO_SIM**

Hidden networks

Hidden networks must be prespecified at initialization time because the network is not visible in the scan results. Due to the power and privacy implications of hidden networks, the framework supports at most one hidden network globally. Therefore, if another plugin has also requested connectivity to a hidden network, the request of the second plugin will be denied. If the plugin requires a hidden network to be configured, it must specify the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability for that network.

For all other networks, the plugin should specify the **HS_FLAG_CAPABILITY_NETWORK_TYPE_VISIBLE** capability.

User interface display strings

Custom UI display strings, used by the plugin to communicate with the user, must be stored in a string table (in an .rc file). The plugin must pass the string IDs to the hotspot offload service to enable it to load the appropriate strings. Currently, the following display strings are supported:

- Provider name (up to **HS_CONST_MAX_PROVIDER_NAME_LENGTH** length)
- Network name (up to **HS_CONST_MAX_NETWORK_DISPLAY_NAME_LENGTH** length)
- Message on the Advanced page (up to **HS_CONST_MAX_ADVANCED_PAGE_STRING_LENGTH** length)
- Any additional strings passed to the user using the HSHostSendUserMessage function (up to **MAX_PATH** length). For more information, see HS_HOST_SEND_USER_MESSAGE.

Note: For more information about Wi-Fi Hotspot Offloading capabilities and constants, see Wi-Fi Hotspot Offloading Constants.

Implementing the plugin

The plugin is implemented as a DLL. The functions HSPluginGetVersion and HSPluginInitPlugin must be exposed either by specifying them in the .def file of the plugin DLL, or by adding the "__declspec(dllexport)" keyword to them in the function implementation.

Initialization

The plugin APIs are invoked in the following order at initialization:

HsPluginGetVersion

The plugin should return its version information, to verify that the plugin version matches the host device version. The current version is stored in the constant **HS_CONST_HOST_CURRENT_API_VERSION**.

HSPluginInitPlugin

This is the main initialization function. It provides the following information to the plugin:

- A context handle for the plugin to use whenever it calls any of the hotspot plugin host (**HS_HOST_****) functions
- The version number currently used by the host (**dwVerNumUsed**)
- Information about the device (**pDeviceIdentity**)
- The OS capabilities available to the plugin, specified as a HS_FLAG_CAPABILITY_NETWORK_** type (**dwHostCapabilities**)
- Handlers for the functions used by the plugin to call back to the host (**pHotspotHostHandlers**)

The plugin returns the following information to the hotspot plugin host:

- A pointer to the structure that contains the list of plugin APIs (**pHotspotPluginAPIs**). For more information, see HOTSPOT_PLUGIN_APIS.
- A pointer to the structure that contains the plugin profile (**pPluginProfile**). For more information, see HS_PLUGIN_PROFILE.

The profile includes all of the capabilities required by the plugin. This is represented by a single value that results from combining the applicable capability flag values (HS_FLAG_CAPABILITY_NETWORK_*) by using a bitwise OR operation. If the plugin specifies the HS_FLAG_CAPABILITY_NETWORK_AUTH_HTTP capability or the HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_* capabilities, the **dwSupportedSIMCount** member of the **HS_PLUGIN_PROFILE** structure must be set to the number of supported

SIMs. The plugin must also specify the total number of networks that it supports by setting the **dwNumNetworksSupported** member of its **HS_PLUGIN_PROFILE** structure.

HsPluginQueryHiddenNetwork [Optional]

If the plugin specifies the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability and the device can support a hidden network, this function is called by the hotspot plugin host to obtain the hidden network information from the plugin. For more information, see HS_PLUGIN_QUERY_HIDDEN_NETWORK.

HsPluginQuerySupportedSIMs [Optional]

The hotspot plugin host calls this function if the plugin specifies a nonzero value for **dwSupportedSIMCount**. When called, the **pNetworkIdentity** argument should be NULL and the plugin is required to provide the list of all SIMs supported by the plugin. This function may also be called later on to identify SIMs that are associated with each hotspot network (at which time, the **pNetworkIdentity** will be non-NULL). The plugin must provide the list of supported SIMs. For more information, see HS_PLUGIN_QUERY_SUPPORTED_SIMS.

Run time

As networks become visible, the hotspot plugin host queries the plugin for each network to determine if it is a hotspot network.

HSPluginIsHotspotNetwork

The hotspot plugin host calls this function to determine if the specified network is a hotspot network. It passes identifying information about the network (SSID, authentication type, cipher) through a HS_NETWORK_IDENTITY structure. The plugin must return an eHS_NETWORK_STATE enumeration value that indicates the type of network. If it is a hotspot network, then information about the network is returned through a HS_NETWORK_PROFILE structure. For more information, see HS_PLUGIN_IS_HOTSPOT_NETWORK.

HsPluginQuerySupportedSIMs [Optional]

The hotspot plugin host calls this function if the plugin specifies the capabilities **HS_FLAG_CAPABILITY_NETWORK_AUTH_HTTP** or **HS_FLAG_CAPABILITIES_NETWORK_AUTH_EAP** in the *HS_NETWORK_PROFILE* argument of the call to HS_PLUGIN_IS_HOTSPOT_NETWORK. When called in this instance, the pNetworkIdentity argument should be non-NULL and the plugin must provide the list of SIMs supported for the network specified in pNetworkIdentity only. For more information, see HS_PLUGIN_QUERY_SUPPORTED_SIMS.

HSPluginQueryCellularExceptionHosts [Optional]

The hotspot plugin host calls this function if the **dwNumCellularExceptions** field of the HS_NETWORK_PROFILE structure, returned by the plugin, is set to a nonzero value. The plugin must return the list of cellular bearer hosts when called. For more information, see HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS.

Connect time

When a network is deemed connectable, or the network is selected by the user, the following sequence of calls takes place:

HSPluginPreConnectInit

The hotspot plugin host calls this function to notify the plugin that a connection to the hotspot network specified in the HS_NETWORK_IDENTITY structure, returned by the plugin, is in progress. For more information, see HS_PLUGIN_PRE_CONNECT_INIT.

HSPluginStartPostConnectAuth

When the L2 connection is complete, the hotspot plugin host calls this function to notify the plugin to start authentication. The plugin is provided the *pConnectContext*, *pNetworkIdentity*, and *pNetworkProfile* from the previous call to **HSPluginPreConnectInit**, but it is also provided a *dwConnectionId* and *pSIMData*. The plugin must store the Connection ID and use it when calling back the host's **HSHostPostConnectAuthCompletion** handler to notify the OS of the authentication result, and also in the call to **HSHostSendUserMessage** if a message needs to be conveyed to the user. The **pSIMData** struct contains addition information about the SIM configuration that could be needed by the plugin during authentication. If the plugin returns Success, it must call **HSHostPostConnectAuthCompletion** within 5 minutes or the connection is disconnected.

Disconnect and reset

When a network is disconnected, either explicitly by some user or device action or implicitly as a result of external factors, the following functions are called:

HSPluginStopPostConnectAuth

The hotspot plugin host calls this function to terminate network authentication because the device is about to be disconnected from the network. For more information, see HS_PLUGIN_STOP_POST_CONNECT_AUTH.

HSPluginDisconnectFromNetwork

The hotspot plugin host calls this function to inform the plugin that the device will be disconnected from the network. For more information, see HS_PLUGIN_DISCONNECT_FROM_NETWORK.

HSPluginReset

The hotspot plugin host calls this function to reset the plugin to its initial (just loaded) state. For more information, see HS_PLUGIN_RESET.

Periodic calls

The following functions are called periodically, depending on specific parameters set by the plugin:

HSPluginSendKeepAlive [Optional]

The hotspot plugin host calls this function at the frequency specified in the **dwKeepAliveTimeMins** member of the HS_NETWORK_PROFILE structure returned by the plugin. For more information, see HS_PLUGIN_SEND_KEEP_ALIVE.

HSPluginCheckForUpdates [Optional]

The hotspot plugin host calls this function at the frequency specified in the **dwProfileUpdateTimeDays** member of the HS_PLUGIN_PROFILE structure.

Unloading the plugin

HSPluginDeinit

The hotspot plugin host calls this function to enable the plugin to flush any unsaved information and close any open handles before it is unloaded. The plugin will be provided the reason for the unload in the *UnloadReason* argument. For more information, see HS_PLUGIN_DEINIT.

Plugin Installation package

THe plugin installation package should include the following:

The Plugin DLL File

The DLL file must be signed and placed under **Programs\HotspotHost\** *<ProviderName>*, where *<ProviderName>* is the name of the DLL provider.

For information about signing the DLL, see Sign binaries and packages.

There is no particular convention for naming the DLL file, so making sure the path to the file is correct in the registry is all that is required. For example, the registry information could be specified in the package as:

```XML
<RegKeys>
        <RegKey KeyName="$(hklm.software)\Microsoft\Windows
Phone\HotspotOffload\Plugins\<ProviderName>">
          <RegValue Name="PluginRank" Type="REG_DWORD" Value="00000005" />
          <RegValue Name="PluginPath" Type="REG_SZ"
Value="%SystemDrive%\Programs\HotspotHost\Orange\<ProviderName>\
<HotspotPlugin.dll>" />
        </RegKey>
      </RegKeys>
```

Registry configuration

The required registry settings are saved in a new entry created under: **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows Phone\HotspotOffload\Plugins\** *ProviderName*.

ProviderName must be unique to the plugin provider or Mobile Operator.

The following values must be saved under the registry key:

Name	Type	Description

Name	Type	Description
PluginPath	[REG_SZ]	The name and full path to the DLL.
PluginRank	[REG_DWORD]	Any positive value between 1 and 250, inclusive (0 is reserved for Microsoft). A lower value represents a higher priority. If two plugins have the same rank, the hotspot service arbitrarily prioritizes one over another.

Data files that contain connection-specific information such as a list of SSIDs, encrypted credentials, etc. [Optional]

The data files should be saved under: `Data\SharedData\HotspotHost\Plugins\<ProviderName>`.

Wi-Fi Discovery Service Overview

Article • 12/15/2021

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The Wi-Fi discovery service enables users to reduce data costs by offloading cellular traffic to Wi-Fi hotspots. The discovery service aggregates Wi-Fi hotspot data from providers, such as mobile operators, and other sources to produce a directory of known Wi-Fi hotspots. By using this directory, users can obtain information about hotspots near their current position.

Mobile operators can submit hotspot data to the service by sending an HTTP POST request, or by using a command-line tool provided by Microsoft.

Instructions

Wi-Fi hotspot data must be in the format described in Wi-Fi Hotspot Data Submission Format.

The discovery service requires that all of a provider's hotspots are submitted in a single batch. Each batch can contain multiple submission requests with a smaller amount of data. For example, a batch containing 1,000 hotspots can be uploaded to the discovery service by sending 10 submission requests, each containing data for 100 hotspots. Each submission request is assigned the same batch number. The final submission request must include a `X-FinalBatchRequest` header set to the total number of hotspots in the batch. The batch is not processed until a submission request with this header is received. If the header does not match the number of hotspots in the batch, the submission is not processed.

Submitting hotspot data by using HTTP POST

The following example shows a typical submission request. The presence of the `X-FinalBatchRequest` header and the numeric value of "1" indicate that there is only one hotspot in this batch and this is the final submission request. Therefore, this is the only submission request. If the batch contained multiple hotspots, this line should be removed for all submission requests but the last one.

```HTTP
POST https://submitwifiservice.windowsphone.com/v1/SubmitHotspots HTTP/1.1
Content-Type: application/json
X-FinalBatchRequest: 1
 [More headers…]
{
      "Header": {
            "BatchId": "2E20A8DB-9AFA-4A5A-AF6E-5F87DA639C15",
            "TransactionId": 1,
            "ProviderId": "FD9E5EE6-75C7-4A54-8B29-45A3FC83AD63"
      },
      "Hotspots": {
            "add": {
                  "Address": "123 abc street",
                  "City": "Redmond",
                  "CountryOrRegion": "USA",
                  "PostalCode": "98052",
                  "StateOrProvince": "WA"
            },

            "bssids":["00:aa:bb:cc:dd:ee"],
            "free": true,
            "pub": true,
            "loc": {
                  "Latitude": 47.01,
                  "Longitude": 121.1234,
                  "RadialUncertainty": 300,
                  "Altitude": 638.34,
                  "AltitudeUncertainty": 100.0
            },
            "name": "Joes Coffee Shop",
            "phid": "abcdefg",
            "ran": 100,
            "ssid": "JoesCoffee",
            "phone": ["425-882-8080"]
      }
}
```

When the message is received on the destination server, **SubmitHotspots** validates the request and authenticates the sender before sending the hotspot data to the discovery service.

Submitting hotspot data by using the command line tool

WifiProviderExe.exe is a command-line tool, provided by Microsoft, that takes as input a hotspot data file, converts it to the required format, and uploads it to a specified discovery service server.

To run WiFiProvider.exe, use the following syntax:

Windows Command Prompt

```
WifiProviderExe –DataFile filename -ProviderId GUID -ServiceEndpoint URL -
CustomTransformer filename.dll [-MappingFile filename.xml] [-CertFile
filename.pfx] [-CertPassword password] [-CertSubject name]
```

For example:

Windows Command Prompt

```
WifiProviderExe -DataFile "file.txt" -ProviderId 00000000-0000-0000-0000-
000000000000 -ServiceEndpoint
"https://submitwifiservice.windowsphone.com/v1/SubmitHotspots" -
CustomTransformer "transformer.dll"
```

The following table contains the list of possible parameters for WiFiProvider.exe.

Parameter	Description
DataFile	Required. The name of the file that contains the hotspot data.
ProviderId	Required. The Microsoft-assigned provider ID (a GUID).
ServiceEndpoint	Required. The URL of the discovery service server to which the hotspot data will be uploaded.
CustomerTransformer	Required. The name of the assembly that contains the transformer.
MappingFile	Optional. The mapping file that maps the provider's hotspot data to the format required by the discovery service.
CertFile	Optional. A pointer to the actual pfx file that contains the certificate(s) for authentication. The certificate password parameter (**CertPassword**) must be specified when using this authentication method.
CertPassword	Optional. The password to the certificate specified in **CertFile**.

Parameter	Description
CertSubject	Optional. The subject name of the certificate. It is located in current user's My Cert store. When using this authentication mechanism, **CertFile** and **CertPassword** are not required. However, it is required to create a private key for the certificate and, in the access control list, grant access rights for the key to the account that will use the certificate.

Transformers

The hotspot data can be in any format. However, it is required to specify a "data transformer" that the command-line tool can access to convert the hotspot data to the format required by the discovery service.

The following table shows the sample transformers that are provided with the command-line tool. They can be used to convert specific data formats to the required format.

Transformer	Data Format	Description
Microsoft.Wps.WifiService.ProviderSdk.JsonHotspotDataTransformer.dll	JSON	Your data must conform to the JSON format specified in Wi-Fi Hotspot Data Submission Format.
Microsoft.Wps.WifiService.ProviderSdk.JsonHotspotDataTransformer.dll	Simple Excel	You must supply a mapping file.

Mapping Files

If your hotspot data is in simple Excel format, you must supply an XML file that maps columns in the Excel file to corresponding required JSON elements. The following list shows the allowed column names:

- Latitude
- Longitude
- RadialUncertainty
- Altitude

- AltitudeUncertainty
- HotspotName
- SSID
- Range
- Address
- City
- StateOrProvince
- PostalCode
- CountryOrRegion
- Bssids
- ProviderHotspotId
- IsPublic
- IsFree
- PhoneNumbers

The following example shows a portion of a mapping file. Each **MappingRule** element associates an Excel column (**PartnerColumnName** and **PartnerColumnNumber**) with a required JSON element (**MicrosoftColumnName**). The **ContainsHeaderRow** element, located after the closing Rules tag (`</Rules>`), indicates that the file contains a header row, which should be skipped when reading data.

XML

```xml
<?xml version="1.0" encoding="utf-8"?>
<MappingRules xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <Rules>
    <MappingRule>
      <PartnerColumnName>english_hotspot_name</PartnerColumnName>
      <PartnerColumnNumber>3</PartnerColumnNumber>
      <MicrosoftColumnName>HotspotName</MicrosoftColumnName>
    </MappingRule>
    <MappingRule>
      <PartnerColumnName>english_city_name</PartnerColumnName>
      <PartnerColumnNumber>2</PartnerColumnNumber>
      <MicrosoftColumnName>City</MicrosoftColumnName>
    </MappingRule>
    <MappingRule>
      <PartnerColumnName>ssid</PartnerColumnName>
      <PartnerColumnNumber>4</PartnerColumnNumber>
      <MicrosoftColumnName>SSID</MicrosoftColumnName>
    </MappingRule>
    <MappingRule>
      <PartnerColumnName>venue</PartnerColumnName>
      <PartnerColumnNumber>7</PartnerColumnNumber>
      <MicrosoftColumnName>HotspotType</MicrosoftColumnName>
    </MappingRule>
        .
        .
        .
        .
  </Rules>
  <ContainsHeaderRow>true</ContainsHeaderRow>
</MappingRules>
```

Wi-Fi Hotspot Data Submission Format

Article • 12/15/2021

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

Hotspot data submitted to the discovery service must be in JavaScript Object Notation (JSON) and must use the following elements.

Element	Type	Description
BatchId	GUID	A provider can split a single submission that contains multiple hotspots into multiple submissions. Each submission is assigned the same BatchId GUID.
ProviderId	GUID	The provider ID will be assigned to the provider by Microsoft.
TransactionId	int	An incrementing number for each request in the batch. Used for degbugging purposes.
Hotspots		A list of hotspots to upload.
add		The full address property, which includes the following sub-elements: **Address**, **City**, **StateOrProvince**, **PostalCode**, and **CountryOrRegion**.
bssids	List<string>	A list of the BSSIDs that make up the hotspot. Each BSSID consists of eight two digit hexadecimal values in the in the following format: *00:aa:bb:cc:dd:ee*.
free	Boolean	A Boolean value that indicates whether the hotspot is free.
pub	Boolean	A Boolean value that indicates whether the hotspot is public.
loc		The full location property which includes the following sub-elements: **Latitude**, **Longitude**, **RadialUncertainty**, **Altitude**, and **AltitudeUncertainty**.

Element	Type	Description
name	string	The friendly name of the hotspot.
phid	string	The provider's hotspot ID. Used for debugging purposes.
ran	uint	The range of the hotspot.
ssid	string	The hotspot's SSID.
phone	string	A list of all the phone numbers associated with the hotspot.

Note

- The header and its sub-elements (**ProviderId**, **BatchId**, and **TransactionId**) are required.
- The Hotspots list must not be empty.
- If the Location element is specified then **Latitude** and **Longitude** are required.
- If the Location element is not specified then at least one BSSID must be specified. Otherwise, a warning will be returned and the discovery service will not process the hotspot.

The following example shows the complete data for a single hotspot:

JSON

```
{
      "Header": {
            "BatchId": "BA85A383-5943-4D84-8ACB-B113BDEA3783",
            "ProviderId": "AE012377-B0B4-4096-B5D5-D7EFBDC170EC",
            "TransactionId": 1
      },
      "Hotspots":[{
            "add": {
                  "Address": "123 abc street",
                  "City": "Redmond",
                  "CountryOrRegion": "USA",
                  "PostalCode": "98052",
                  "StateOrProvince": "WA"
            },
            "bssids":["00:aa:bb:cc:dd:ee"],
            "free": true,
            "pub": true,
            "loc": {
                  "Latitude": 47.01,
                  "Longitude": 121.1234,
                  "RadialUncertainty": 300,
                  "Altitude": 638.34,
                  "AltitudeUncertainty": 100.0
            },
            "name": "Joes Coffee Shop",
            "phid": "abcdefg",
            "ran": 100,
            "ssid": "JoesCoffee",
            "phone": ["425-882-8080"]
      }
}
```

The discovery service returns a simple response, also in JSON format, that includes the activity ID used for debugging purposes and a list of warnings that were generated when the discovery service validated the hotspot data. All strings returned by the discovery service are encoded in UTF-8.

The following table shows the JSON elements for a discovery service response.

Element	Type	Description
ActivityId	string	Required. This is a string that the provider can use to help debug issues.
Warnings	List<string>	A human-readable list of warnings.

The following example shows a typical response to a hotspot data submission:

```JSON
{
    "ActivityId": "d2856c06-e4a1-4434-90e8-ced0c9ee6e10",
    "Warnings": ["Invalid Latitude: 247.67 – Hotspot Id: abcdefg"]
}
```

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

This section describes the constants that are defined for the Wi-Fi Hotspot Offloading framework.

HS_CONST_HOST_CURRENT_API_VERSION
1
Current API version number.

HS_CONST_MAX_NETWORK_DISPLAY_NAME_LENGTH
32
Maximum length of the network display name string.

HS_CONST_MAX_REALM_LENGTH
255
Maximum length of the realm value string.

HS_CONST_MIN_CONN_KEEPALIVE_TIME_IN_MINS
5
Minimum time between keep-alive message transmissions

HS_CONST_PROFILE_UPDATE_TIME_IN_DAYS
7
Minimum time between checks for profile updates.

HS_CONST_MIN_NETWORK_PRIORITY_VALUE
1
Minimum network priority value.

HS_CONST_MAX_NETWORK_PRIORITY_VALUE

65000

Maximum network priority value.

HS_MAX_PHONE_NUMBER_LENGTH

32

Maximum length of the phone number string.

HS_CONST_MAX_HOST_NAME_LENGTH

255

Maximum length of the host name string.

HS_CONST_PLUGIN_MIN_RANK_VALUE

1

Minimum Rank value. Must be greater than 0.

HS_CONST_PLUGIN_MAX_RANK_VALUE

250

Maximum rank value. Must be less than or equal to 250.

HS_CONST_MAX_PROVIDER_NAME_LENGTH

63

Maximum length of provider name string.

HS_CONST_MAX_ADVANCED_PAGE_STRING_LENGTH

255

Maximum length of the advanced page string.

HS_CONST_MAX_PHONE_NUMBER_LENGTH

32

Maximum length of the phone number string.

HS_CONST_MAX_SUPPORTED_SIMS

1000

Maximum size of the list of supported SIM configurations.

HS_CONST_MAX_CELLULAR_EXCEPTION_HOSTS

5

Maximum size of the list of cellular bearers.

HS_CONST_MAX_AUTH_ERROR_MSG_LENGTH

512

Maximum length of an authentication error message.

HS_CONST_MAX_USER_MESSAGES_IN_MINUTES
7*24*60
Maximum user messages, in minutes (7 days).

The following flags are defined for the plug-in and the host to indicate their requirements and capabilities respectively.

HS_FLAG_CAPABILITY_NETWORK_TYPE_VISIBLE
0x00000001
Specifies visible network.

HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN
0x00000002
Specifies hidden network.

HS_FLAG_CAPABILITY_NETWORK_DISPLAY_NAME
0x00000010
Specifies use of display name for EAP-SIM or EAP-AKA authentication.

HS_FLAG_CAPABILITY_NETWORK_AUTH_NO_SIM
0x00000100
Specifies no-SIM authentication.

HS_FLAG_CAPABILITY_NETWORK_AUTH_HTTP
0x00000200
Specifies HTTP authentication.

HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_SIM
0x00001000
Specifies EAP-SIM authentication.

HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_AKA
0x00002000
Specifies EAP-AKA authentication.

HS_FLAG_CAPABILITY_NETWORK_AUTH_EAP_AKA_PRIME
0x00004000
Specifies EAP-AKA’ (AKA Prime) authentication.

HS_FLAG_CAPABILITY_NETWORK_CUSTOM_REALM
0x00010000
Specifies use of custom realm value for network authentication.

Wi-Fi Hotspot Offloading Reference

HOTSPOT_HOST_HANDLERS structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HOTSPOT_HOST_HANDLERS** structure contains the hotspot host handlers function table. This function table is passed to the plugin when HSPluginInitPlugin is called to initialize it. The table contains functions that are called by the plugin to communicate with the hotspot host.

Syntax

ManagedCPlusPlus

```
typedef struct _HOTSPOT_HOST_HANDLERS {
  HS_HOST_ALLOCATE_MEMORY                            HSHostAllocateMemory;
  HS_HOST_FREE_MEMORY                                HSHostFreeMemory;
  HS_HOST_POST_CONNECT_AUTH_COMPLETION
            HSHostPostConnectAuthCompletion;
  HS_HOST_SEND_KEEP_ALIVE_COMPLETION
              HSHostSendKeepAliveCompletion;
  HS_HOST_UPDATE_CONFIGURATION_COMPLETION
         HSHostUpdateConfigurationCompletion;
  HS_HOST_SEND_USER_MESSAGE                          HSHostSendUserMessage;
} HOTSPOT_HOST_HANDLERS, *PHOTSPOT_HOST_HANDLERS;
```

Members

HSHostAllocateMemory

Optional memory management handler.

Handle to the function that is called by the plugin to allocate any memory needed by the plugin. For more information, see HS_HOST_ALLOCATE_MEMORY.

HSHostFreeMemory
Optional memory management handler.

Handle to the function that is called by the plugin to free any memory that had been allocated earlier by the call to HS_HOST_ALLOCATE_MEMORY. For more information, see HS_HOST_FREE_MEMORY.

HSHostPostConnectAuthCompletion
Required connection-process handler.

Handle to the function that is called by the plugin to indicate the success or failure status resulting from the authentication attempt following a Wi-Fi connection setup at layer 2. For more information, see HS_PLUGIN_START_POST_CONNECT_AUTH.

HSHostSendKeepAliveCompletion
Optional periodic request.

Handle to the function that is called by the plugin to indicate the success or failure status resulting from the Send Keep Alive request. For more information, see HS_PLUGIN_SEND_KEEP_ALIVE.

HSHostUpdateConfigurationCompletion
Optional periodic request.

Handle to the function that is called by the plugin to indicate the success or failure of a call to check for updates. For more information, see HS_PLUGIN_CHECK_FOR_UPDATES.

HSHostSendUserMessage
Optional periodic request.

Handle to the function that is called to communicate with the user. For more information see HS_HOST_SEND_USER_MESSAGE.

Requirements

HOTSPOT_PLUGIN_APIS structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HOTSPOT_PLUGIN_APIS** structure contains the Hotspot plugin APIs function table. This function table is returned by the plugin when HSPluginInitPlugin is called to initialize the plugin. The table contains functions that are called by the hotspot host to communicate with the plugin.

Syntax

ManagedCPlusPlus

```
typedef struct _HOTSPOT_PLUGIN_APIS {
  HS_PLUGIN_QUERY_SUPPORTED_SIMS     HSPluginQuerySupportedSIMs;
  HS_PLUGIN_QUERY_HIDDEN_NETWORK     HSPluginQueryCellularExceptionHosts;
  HS_PLUGIN_IS_HOTSPOT_NETWORK       HSPluginIsHotspotNetwork;
  HS_PLUGIN_PRE_CONNECT_INIT         HSPluginPreConnectInit;
  HS_PLUGIN_START_POST_CONNECT_AUTH  HSPluginStartPostConnectAuth;
  HS_PLUGIN_STOP_POST_CONNECT_AUTH   HSPluginStopPostConnectAuth;
  HS_PLUGIN_DISCONNECT_FROM_NETWORK  HSPluginDisconnectFromNetwork;
  HS_PLUGIN_RESET                    HSPluginReset;
  HS_PLUGIN_SEND_KEEP_ALIVE          HSPluginSendKeepAlive;
  HS_PLUGIN_CHECK_FOR_UPDATES        HSPluginCheckForUpdates;
  HS_PLUGIN_DEINIT                   HSPluginDeinit;
} HOTSPOT_PLUGIN_APIS, *PHOTSPOT_PLUGIN_APIS;
```

Members

HSPluginQuerySupportedSIMs
API called during plugin initialization.

Called by the hotspot host to retrieve the list of SIMs that the plugin supports. It can be called to retrieve the complete list of supported SIMs, or just the SIMs for a specific network. For more information, see HS_PLUGIN_QUERY_SUPPORTED_SIMS.

HSPluginQueryCellularExceptionHosts
API called during plugin initialization.

Called by the hotspot host if the plugin has specified the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability by way of the HS_PLUGIN_PROFILE structure. For more information, see HS_PLUGIN_QUERY_HIDDEN_NETWORK.

HSPluginIsHotspotNetwork
API called while processing scan results.

Called by the hotspot host to request the plugin to identify if the network passed in the *pHiddenNetworkIdentity* parameter is a hotspot network. For more information, see HS_PLUGIN_IS_HOTSPOT_NETWORK.

HSPluginPreConnectInit
Connection-process API.

Called by the hotspot host to notify the plugin to initialize its state when a connection is in progress. For more information, see HS_PLUGIN_PRE_CONNECT_INIT.

HSPluginStartPostConnectAuth
Connection-process API.

Called by the hotspot host to request the plugin to perform any post-connect authentication required to authenticate the device over the network. For more information, see HS_PLUGIN_START_POST_CONNECT_AUTH.

HSPluginStopPostConnectAuth
Connection-process API.

Called by the hotspot host to notify the plugin to stop the authentication process. For more information, see HS_PLUGIN_STOP_POST_CONNECT_AUTH.

HSPluginDisconnectFromNetwork
Connection-process API.

Called by the hotspot host to notify the plugin of disconnection from network. For more information, see HS_PLUGIN_DISCONNECT_FROM_NETWORK.

HSPluginReset
API to reset the plugin. If the plugin does not release any pending calls before returning from this call, the plugin will be unloaded.

Called by the hotspot host to reset the plugin. For more information, see HS_PLUGIN_RESET.

HSPluginSendKeepAlive
API for plugin to do periodic updates.

Called by the hotspot host to send a keep-alive message to the plugin. For more information, see HS_PLUGIN_SEND_KEEP_ALIVE.

HSPluginCheckForUpdates
API for plugin to do periodic updates.

Called by the hotspot host to check for updates. For more information, see HS_PLUGIN_CHECK_FOR_UPDATES.

HSPluginDeinit
API called to de-initialize and clean up the plugin before unloading.

Called by the hotspot host to notify the plugin that it is about to be unloaded. For more information, see HS_PLUGIN_DEINIT.

> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_CONNECTION_CONTEXT** structure contains the information required by the plugin for post connect authentication.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_CONNECTION_CONTEXT {
  HS_MAC_ADDRESS  MacAddress;
  HS_SIM_IDENTITY SIMIdentity;
  WCHAR           pszPhoneNumber[HS_MAX_PHONE_NUMBER_LENGTH+1];
} HS_CONNECTION_CONTEXT, *PHS_CONNECTION_CONTEXT;
```

Members

MacAddress
The HS_MAC_ADDRESS structure that contains the MAC address.

SIMIdentity
The HS_SIM_IDENTITY structure that contains information required for EAP-SIM/AKA authentication.

pszPhoneNumber
Pointer to the phone number.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_DEVICE_IDENTITY** structure contains information about the device model and manufacturer.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_DEVICE_IDENTITY {
  DWORD dwSystemType;
  WCHAR wszPhoneManufacturer[HS_CONST_MAX_DEVICE_INFO_LENGTH+1];
  WCHAR wszPhoneModelName[HS_CONST_MAX_DEVICE_INFO_LENGTH+1];
  WCHAR wszPhoneManufacturerModel[HS_CONST_MAX_DEVICE_INFO_LENGTH+1];
  WCHAR wszDeviceModel[HS_CONST_MAX_DEVICE_INFO_LENGTH+1];
} HS_DEVICE_IDENTITY, *PHS_DEVICE_IDENTITY;
```

Members

dwSystemType
The type of SIM, whether GSM or CDMA.

wszPhoneManufacturer
The phone manufacturer name.

wszPhoneModelName
The phone model name.

wszPhoneManufacturerModel

Another name for the phone manufacturer and model.

wszDeviceModel

The device model name.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_MAC_ADDRESS structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_MAC_ADDRESS** structure contains the host Media Access Control (MAC) address.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_MAC_ADDRESS {
  UCHAR ucHSMacAddress[6];
} HS_MAC_ADDRESS, *PHS_MAC_ADDRESS;
```

Members

ucHSMacAddress
The MAC address.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_NETWORK_IDENTITY structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_NETWORK_IDENTITY** structure contains information that uniquely identifies a Wi-Fi network.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_NETWORK_IDENTITY {
  HS_SSID             Ssid;
  HS_AUTH_ALGORITHM   hsAuthAlgo;
  HS_CIPHER_ALGORITHM hsCipherAlgo;
} HS_NETWORK_IDENTITY, *PHS_NETWORK_IDENTITY;
```

Members

Ssid
The network SSID.

hsAuthAlgo
The authentication algorithm used by the wireless network.

hsCipherAlgo
The cipher algorithm used by the wireless network.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_NETWORK_PROFILE structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_NETWORK_PROFILE** structure is provided by the plugin and contains information required for connection to the target network. Each instance of the Network Profile is uniquely associated with a corresponding HS_NETWORK_IDENTITY structure.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_NETWORK_PROFILE {
  DWORD  dwNetworkCapabilities;
  USHORT usPriority;
  DWORD  dwSupportedSIMCount;
  DWORD  dmNumCellularExceptions;
  DWORD  dwNetworkStringID;
  DWORD  dwKeepAliveTimeMins;
  WCHAR  szRealm[HS_CONST_MAX_REALM_LENGTH+1];
} HS_NETWORK_PROFILE, *PHS_NETWORK_PROFILE;
```

Members

dwNetworkCapabilities

A subset of the possible **HS_FLAG_CAPABILITY_NETWORK_*** values. For more information about hotspot host capabilities, see Wi-Fi Hotspot Offloading Constants.

usPriority

A unique priority value assigned to the associated network. It must be a value between 1 and 65000 (a hidden network must have a value of 1). A lower numeric value corresponds to a higher priority.

dwSupportedSIMCount
Supported SIM count. This member is set for HTTP-based and EAP-SIM/AKA/AKA' authentication.

dmNumCellularExceptions
Optional. Number of host connections over cellular only.

dwNetworkStringID
Network name string ID. Maximum string size = MAX_NETWORK_DISPLAY_NAME_LENGTH.

dwKeepAliveTimeMins
Optional. The time interval between network connection keep-alive messages.

szRealm
Network-specific realm value.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

Wi-Fi Hotspot Offloading Constants

HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS** structure contains the list of hosts that the plugin requires to be connected over a cellular bearer only during the authentication process. This is an optional capability that can be requested by the plugin. For more information, see HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS {
  DWORD               dwCount;
  HS_PLUGIN_HOST_NAME pExceptions[*];
  HS_PLUGIN_HOST_NAME pExceptions[1];
} HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS, *PHS_PLUGIN_CELLULAR_EXCEPTION_HOSTS;
```

Members

dwCount

The number of host names in the list pointed to by **pExceptions**.

pExceptions

Used if MIDL is utilized. Unique, size is (dwCount).

Pointer to the list of host names.

pExceptions

Used if MIDL is not utilized.

Pointer to the list of host names.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

See also

HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS

Microsoft Interface Definition Language

HS_PLUGIN_HOST_NAME structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_HOST_NAME** structure contains the host name.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_PLUGIN_HOST_NAME {
  WHCAR pszHostName[HS_CONST_MAX_HOST_NAME_LENGTH+1];
} HS_PLUGIN_HOST_NAME, *PHS_PLUGIN_HOST_NAME;
```

Members

pszHostName
Pointer to the host name.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_PROFILE structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_PROFILE** structure provides information about the plugin. The members of this structure are set by the plugin during execution of the HSPluginInitPlugin function that is called by the host.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_PLUGIN_PROFILE {
  DWORD dwPluginCapabilities;
  DWORD dwNumNetworksSupported;
  DWORD dwProviderNameStringID;
  DWORD dwGenericNetworkNameStringID;
  DWORD dwAdvancedPageStringID;
  DWORD dwProfileUpdateTimeDays;
  WCHAR szRealm[HS_CONST_MAX_REALM_LENGTH+1];
  DWORD dwSupportedSIMCount;
} HS_PLUGIN_PROFILE, *PHS_PLUGIN_PROFILE;
```

Members

dwPluginCapabilities
Required.

A subset of the possible **HS_FLAG_CAPABILITY_NETWORK_*** values. For more information about hotspot host capabilities, see Wi-Fi Hotspot Offloading Constants.

dwNumNetworksSupported
Required.

Total number of networks supported by this plugin.

dwProviderNameStringID
Required.

The network provider name which is displayed to the user. Maximum string size = MAX_PROVIDER_NAME_LENGTH.

dwGenericNetworkNameStringID
Optional.

Network name. Maximum string size = MAX_NETWORK_DISPLAY_NAME_LENGTH.

dwAdvancedPageStringID
Optional.

Maximum string size = HS_CONST_MAX_ADVANCED_PAGE_STRING_LENGTH.

dwProfileUpdateTimeDays
Optional.

Must be greater than or equal to HS_CONST_MIN_PROFILE_UPDATE_TIME_IN_DAYS.

szRealm
Required if HS_FLAG_CAPABILITIES_NETWORK_CUSTOM_REALM is set.

Network-specific realm value.

dwSupportedSIMCount
The size of the list pointed to by **pSupported SIMs**.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HSPluginInitPlugin

Wi-Fi Hotspot Offloading Constants

HS_PLUGIN_SUPPORTED_SIMS structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_SUPPORTED_SIMS** structure contains the list of supported SIM configurations. This list must be supplied if the hotspot plugin requires HTTP or EAP authentication for any of its networks.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_PLUGIN_SUPPORTED_SIMS {
  DWORD           dwCount;
  HS_SIM_IDENTITY pSupportedSIMs[*];
  HS_SIM_IDENTITY pSupportedSIMs[1];
} HS_PLUGIN_SUPPORTED_SIMS, *PHS_PLUGIN_SUPPORTED_SIMS;
```

Members

dwCount

The list size.

pSupportedSIMs

Used if MIDL is utilized. Unique, size is (dwCount).

An array of HS_SIM_IDENTITY structures that make up the list of supported SIM configurations.

pSupportedSIMs

Used if MIDL is not utilized.

An array of HS_SIM_IDENTITY structures that make up the list of supported SIM configurations.

Remarks

In the **dwEapMethods** field of the **HS_SIM_IDENTITY** structure for each SIM configuration, you must specify the EAP methods that it supports.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

See also

Microsoft Interface Definition Language

HS_PLUGIN_VERSION structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_VERSION** structure contains the minimum and maximum hotspot host versions supported by the plugin.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_PLUGIN_VERSION {
  DWORD dwVerMin;
  DWORD dwVerMax;
} HS_PLUGIN_VERSION, *PHS_PLUGIN_VERSION;
```

Members

dwVerMin
The minimum hotspot host version supported by the plugin.

dwVerMax
The maximum hotspot host version supported by the plugin.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_SIM_DATA structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_SIM_DATA** structure contains information stored in the SIM card.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_SIM_DATA {
  WCHAR wszICCID[HS_CONST_MAX_ICCID_LENGTH+1];
  WCHAR wszIMEI[HS_CONST_MAX_IMEI_LENGTH+1];
  WCHAR wszMEID_ME[HS_CONST_MAX_MEID_ME_LENGTH+1];
  WCHAR wszSF_EUIMID[HS_CONST_MAX_SF_EUIMID_LENGTH+1];
} HS_SIM_DATA, *PHS_SIM_DATA;
```

Members

wszICCID

The Integrated Circuit Card Identifier (ICCID) stored in the SIM card.

wszIMEI

The International Mobile Equipment Identity (IMEI) used to identify 3GPP phones.

wszMEID_ME

The Mobile Equipment Identifier (MEID) defined by 3GPP2.

wszSF_EUIMID

The Short Form Expanded User Identity Module Identifier (EUIMID) for a R-UIM or CSIM

(CDMA SIM application) card.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_SIM_IDENTITY structure

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_SIM_IDENTITY** structure contains SIM identification information required for EAP-SIM or EAP-AKA authentication.

Syntax

ManagedCPlusPlus

```
typedef struct _HS_SIM_IDENTITY {
  eHS_SIM_TYPE SimType;
  DWORD        dwMNC;
  DWORD        dwMCC;
  DWORD        dwNID;
  DWORD        dwSID;
  DWORD        dwEapMethods;
} HS_SIM_IDENTITY, *PHS_SIM_IDENTITY;
```

Members

SimType

The type of SIM, whether GSM or CDMA, or none. If the network is GSM, the **dwMNC** and **dwMCC** pair of fields will be defined, whereas for CDMA the **dwSID** and **dwNID** pair of fields must be defined.

dwMNC

Used if the SIM is GSM type.

The mobile network code (MNC) of the GSM network.

dwMCC
Used if the SIM is GSM type.

The mobile country code (MCC) of the GSM network.

dwNID
Used if the SIM is CDMA type.

The Network Identification Number (NID) of the CDMA network.

dwSID
Used if the SIM is CDMA type.

The System Identification Number (SID) of the CDMA network.

dwEapMethods
The EAP authentication method.

Requirements

Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HSPluginGetVersion function

> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HSPluginGetVersion** function is exported by the plugin DLL and is called to verify that the plugin version matches the host version.

Syntax

ManagedCPlusPlus

```
DWORD HSPluginGetVersion(
  _Out_ HS_PLUGIN_VERSION *pHotspotPluginVersion
);
```

Parameters

**pHotspotPluginVersion* [out]
A pointer to the HS_PLUGIN_VERSION structure that contains version information for the plugin.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

See also

HS_PLUGIN_VERSION

HSPluginInitPlugin function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HSPluginInitPlugin** function is exported by the plugin DLL and is called to initialize the plugin.

Syntax

ManagedCPlusPlus

```
DWORD HSPluginInitPlugin(
  _In_  HANDLE                hPluginContext,
  _In_  DWORD                 dwVerNumUsed,
  _In_  DWORD                 dwHostCapabilities,
  _In_  HS_DEVICE_IDENTITY    *pDeviceIdentity,
  _In_  HOTSPOT_HOST_HANDLERS *pHotspotHostHandlers,
  _Out_ HOTSPOT_PLUGIN_APIS   *pHotspotPluginAPIs,
  _Out_ HS_PLUGIN_PROFILE     *pPluginProfile
);
```

Parameters

hPluginContext [in]
A handle, provided by the host, that the plugin is required to save and then use when it needs to make a request to the host by way of the host handler functions.

dwVerNumUsed [in]
The host's current version number.

dwHostCapabilities [in]
Value that specifies the list of capabilities that the host can provide to the plugin. This value is the bitwise OR combination of the applicable capability flags. For more information about capability flags, see the **HS_FLAG_CAPABILITY_*** constants in Wi-Fi Hotspot Offloading Constants.

Note If the host does not supply all the capabilities required by the plugin, the plugin will not be initialized.

**pDeviceIdentity* [in]
Pointer to a HS_DEVICE_IDENTITY structure that contains information about the device manufacturer and model.

**pHotspotHostHandlers* [in]
Pointer to a HOTSPOT_HOST_HANDLERS structure that contains the hotspot host handlers function table. This table contains pointers to functions that are called by the plugin to communicate with the hotspot host.

**pHotspotPluginAPIs* [out]
Pointer to the HOTSPOT_PLUGIN_APIS structure that contains the hotspot plugin APIs function table. This table is returned by the plugin and contains pointers to functions that are called by the host to communicate with the plugin.

**pPluginProfile* [out]
Pointer to a HS_PLUGIN_PROFILE structure, returned by the plugin, that provides information about the plugin.

Remarks

During initialization, the host provides the following:

- The plugin context handle
- The current version number
- A list of capabilities that the host can provide to the plugin
- A pointer to the host handler function table through which the plugin can communicate with the host

The plugin returns a pointer to its own function table and a pointer to its HS_PLUGIN_PROFILE structure.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

The **HS_PLUGIN_CHECK_FOR_UPDATES** function checks for configuration updates at the frequency specified in the **dwProfileUpdateTimeDays** member of the plugin's HS_PLUGIN_PROFILE structure.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_CHECK_FOR_UPDATES)(

);
```

Parameters

This function has no parameters.

**

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_DEINIT function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_DEINIT** function is called by the host to notify the plugin that it will be unloaded.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_DEINIT)(
  _In_ eHS_UNLOAD_REASON UnloadReason
);
```

Parameters

UnloadReason [in]
An eHS_UNLOAD_REASON enumeration value that indicates the reason for the unload.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

Upon receiving notification that it will be unloaded, the plugin should complete any current activity and save state, if required.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_DISCONNECT_FROM_NETWORK function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_DISCONNECT_FROM_NETWORK** function notifies the plugin that the device will be disconnected from the network.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_DISCONNECT_FROM_NETWORK)(
  _In_ HS_NETWORK_IDENTITY *pNetworkIdentity
);
```

Parameters

**pNetworkIdentity* [in]
Pointer to the HS_NETWORK_IDENTITY structure for the network from which the device is to be disconnected.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

The **HS_PLUGIN_IS_HOTSPOT_NETWORK** function is called by the host to determine if a specified network is a hotspot network.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_IS_HOTSPOT_NETWORK)(
  _In_      HS_NETWORK_IDENTITY *pNetworkIdentity,
  _Out_     eHS_NETWORK_STATE   *pNetworkState,
  _Out_opt_ HS_NETWORK_PROFILE  *pNetworkProfile
);
```

Parameters

**pNetworkIdentity* [in]
Pointer to the HS_NETWORK_IDENTITY structure for the network from which the device is to be disconnected.

**pNetworkState* [out]
An eHS_NETWORK_STATE enumeration value that indicates the type of network.

**pNetworkProfile* [out, optional]
Pointer to the HS_NETWORK_PROFILE structure for the network.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_PRE_CONNECT_INIT** function is called to notify the plugin to initialize its state when a connection to a hotspot network is in progress.

Syntax

ManagedCPlusPlus

```
typedef DWORD (WINAPI *HS_PLUGIN_PRE_CONNECT_INIT)(
  _In_ HS_NETWORK_IDENTITY *pNetworkIdentity
);
```

Parameters

**pNetworkIdentity* [in]
Pointer to the HS_NETWORK_IDENTITY structure for the target network.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS** function queries the list of hosts that the plugin will need to connect to over cellular as part of its authentication process.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_QUERY_CELLULAR_EXCEPTION_HOSTS)(
  _Inout_ HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS *pExceptionsList
);
```

Parameters

**pExceptionsList* [in, out]
The HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS structure that contains the list of cellular host names.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

This function is called only if the plugin sets the **dwNumCellularExceptions** field of its HS_PLUGIN_PROFILE to a value greater than zero.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

See also

HS_PLUGIN_CELLULAR_EXCEPTION_HOSTS

HS_PLUGIN_PROFILE

HS_PLUGIN_QUERY_HIDDEN_NETWORK function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_QUERY_HIDDEN_NETWORK** function returns the network identity and network profile for a hidden network.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_QUERY_HIDDEN_NETWORK)(
  _Out_ HS_NETWORK_IDENTITY *pHiddenNetworkIdentity,
  _Out_ HS_NETWORK_PROFILE  *pHiddenNetworkProfile
);
```

Parameters

**pHiddenNetworkIdentity* [out]
The HS_NETWORK_IDENTITY structure that uniquely identifies the network.

**pHiddenNetworkProfile* [out]
The HS_NETWORK_PROFILE structure that contains the network profile.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

The host calls this function only if the **dwPluginCapabilities** field of the associated plugin's HS_PLUGIN_PROFILE structure includes the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability.

The plugin must provide both the network identity and the network profile for the hidden Wi-Fi network.

This network must have the highest priority (1) among all the hotspot networks.

The hotspot offload service imposes a limitation of one hidden network for the life of the service. Therefore, in the case where there are multiple plugins installed, only the first plugin's request to specify a hidden network will be accepted.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_QUERY_SUPPORTED_SIMS** function returns the list of SIMs that the plugin supports.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_QUERY_SUPPORTED_SIMS)(
  _In_opt_ HS_NETWORK_IDENTITY      *pNetworkIdentity,
  _Inout_  HS_PLUGIN_SUPPORTED_SIMS *pSupportedSIMs
);
```

Parameters

**pNetworkIdentity* [in, optional]
The HS_NETWORK_IDENTITY structure that uniquely identifies the network.

**pSupportedSIMs* [in, out]
Pointer to an array of one or more HS_PLUGIN_SUPPORTED_SIMS structures that contains the list of supported SIMs.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

If the *pNetworkIdentity* parameter exists then only those SIM identities required for connecting to the specified network must be provided, otherwise the entire list of SIMs for connecting to all networks must be provided.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_RESET** function is called by the host to notify the plugin that it must reset its state.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_RESET)(

);
```

Parameters

This function has no parameters.

**

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

The plugin should terminate all threads and stop any activities in progress.

The plugin is unloaded if it fails to reset.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_SEND_KEEP_ALIVE function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_SEND_KEEP_ALIVE** function is called by the host to send a network connection keep-alive message. It will be called at the frequency specified in the **dwKeepAliveTimeMins** member of the plugin's HS_PLUGIN_PROFILE structure.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_SEND_KEEP_ALIVE)(

);
```

Parameters

This function has no parameters.

**

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

HS_PLUGIN_START_POST_CONNECT_AUTH function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_START_POST_CONNECT_AUTH** function is called to perform any post-connect authentication required to authenticate the device over the network.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_START_POST_CONNECT_AUTH)(
  _In_ DWORD                 dwConnectionId,
  _In_ HS_CONNECTION_CONTEXT *pConnectContext,
  _In_ HS_SIM_DATA           *pSIMData,
  _In_ HS_NETWORK_IDENTITY   *pNetworkIdentity,
  _In_ HS_NETWORK_PROFILE    *pNetworkProfile
);
```

Parameters

dwConnectionId [in]
Unique identifier for the network connection.

**pConnectContext* [in]
Pointer to a HS_CONNECTION_CONTEXT structure that contains the information required by the plugin for post-connect authentication.

**pSIMData* [in]
Pointer to a HS_SIM_DATA structure that contains information from the SIM required by the plugin for post-connect authentication.

**pNetworkIdentity* [in]
Pointer to the HS_NETWORK_IDENTITY structure for the network.

**pNetworkProfile* [in]
Pointer to the HS_NETWORK_PROFILE structure that contains the network profile.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Remarks

After calling this function, the plugin must call the HS_HOST_POST_CONNECT_AUTH_COMPLETION handler to inform the host of the status of the request.

If the network uses EAP-SIM/AKA authentication, the plugin is not expected to perform any activity in this state. However, if the network requires HTTP-based authentication, the plugin must perform the appropriate authentication.

Requirements

> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_PLUGIN_STOP_POST_CONNECT_AUTH** function is called to notify the plugin to stop the authentication process.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_PLUGIN_STOP_POST_CONNECT_AUTH)(
  _In_ HS_NETWORK_IDENTITY *pNetworkIdentity
);
```

Parameters

**pNetworkIdentity* [in]
The HS_NETWORK_IDENTITY structure that uniquely identifies the network.

Return value

This function is called by the host to communicate with the plugin and does not return a value.

Requirements

Version	Windows 10 Mobile

HS_HOST_ALLOCATE_MEMORY function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_ALLOCATE_MEMORY** function returns an amount of memory specified by the caller.

Syntax

ManagedCPlusPlus

```
 (WINAPI *HS_HOST_ALLOCATE_MEMORY)(
  _In_   HANDLE                        hPluginContext,
  _In_   DWORD                         dwByteCount,
  _Out_ _bcount (dwByteCount) LPVOID* ppvBuffer
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

dwByteCount [in]
The amount of memory to allocate.

ppvBuffer [out]
Pointer to the buffer that contains the allocated memory.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_HOST_FREE_MEMORY function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_FREE_MEMORY** function frees any memory that was allocated earlier by a call to HS_HOST_ALLOCATE_MEMORY.

Syntax

ManagedCPlusPlus

```
 typedef VOID (WINAPI *HS_HOST_FREE_MEMORY)(
  _In_     HANDLE hPluginContext,
  _In_opt_ LPVOID pvBuffer
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

pvBuffer [in, optional]
Pointer to the memory buffer.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_HOST_POST_CONNECT_AUTH_COMPLETION function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_POST_CONNECT_AUTH_COMPLETION** function indicates the success or failure of an authentication attempt following a Wi-Fi connection setup at layer 2.

Syntax

ManagedCPlusPlus

```
  typedef DWORD (WINAPI *HS_HOST_POST_CONNECT_AUTH_COMPLETION)(
   _In_     HANDLE                     hPluginContext,
   _In_     DWORD                      dwConnectionId,
   _In_     eHS_AUTHENTICATION_RESULT  AuthResult,
   _In_opt_ LPVOID                     pvReserved
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

dwConnectionId [in]
Unique identifier for the network connection.

AuthResult [in]
The eHS_AUTHENTICATION_RESULT enumeration value that indicates success or failure.

pvReserved [in, optional]
Reserved for future use.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Remarks

The plugin must call this function to inform the host of the result of a previous call to HS_PLUGIN_START_POST_CONNECT_AUTH.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

Wi-Fi Hotspot Offloading deprecation note

> **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_SEND_KEEP_ALIVE_COMPLETION** function indicates the success or failure of a request for a network send keep-alive message.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_HOST_SEND_KEEP_ALIVE_COMPLETION)(
  _In_ HANDLE hPluginContext,
  _In_ DWORD  dwResult
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

dwResult [in]
The result code.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Remarks

The plugin must call this function to inform the host of the result of a previous call to HS_PLUGIN_SEND_KEEP_ALIVE.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_HOST_SEND_USER_MESSAGE function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_SEND_USER_MESSAGE** function is called to communicate with the user. The message content is contained in custom UI display strings that are passed to the hotspot offload service.

Syntax

ManagedCPlusPlus

```
 typedef DWORD (WINAPI *HS_HOST_SEND_USER_MESSAGE)(
  _In_ HANDLE hPluginContext,
  _In_ DWORD  dwConnectionId,
  _In_ DWORD  dwStringID
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

dwConnectionId [in]
Unique identifier for the network connection.

dwStringID [in]
The string ID, used as an index into the string table where the message is stored.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Remarks

The hotspot plugin stores the messages in a string table. The plugin must pass the string IDs to the hotspot offload service to enable it to load the appropriate strings.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_HOST_UPDATE_CONFIGURATION_COMPLETION function

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **HS_HOST_UPDATE_CONFIGURATION_COMPLETION** function indicates the success or failure of a request to check for updates.

Syntax

ManagedCPlusPlus

```
typedef DWORD (WINAPI *HS_HOST_UPDATE_CONFIGURATION_COMPLETION)(
  _In_ HANDLE            hPluginContext,
  _In_ eHS_UPDATE_RESULT UpdateResult
);
```

Parameters

hPluginContext [in]
Context handle for the plugin making the call to this function.

UpdateResult [in]
The eHS_UPDATE_RESULT enumeration value that indicates the result of the request to check for updates.

Return value

This function is called by the plugin to communicate with the host and does not return a value.

Remarks

The plugin must call this function to inform the host of the result of a previous call to HS_PLUGIN_CHECK_FOR_UPDATES.

Requirements

Version	Windows 10 Mobile

Wi-Fi Hotspot Offloading deprecation note

ⓘ Important

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **eHS_AUTHENTICATION_RESULT** enumeration indicates the result of authentication by the plugin after the PostConnectAuth request.

Syntax

ManagedCPlusPlus

```
typedef enum _eHS_AUTHENTICATION_RESULT {
  HS_AUTHENTICATION_RESULT_SUCCESS         = 0,
  HS_AUTHENTICATION_RESULT_FAILED_TIMEOUT  = 100,
  HS_AUTHENTICATION_RESULT_FAILED_AUTH,
  HS_AUTHENTICATION_RESULT_FAILED_CONNECT,
  HS_AUTHENTICATION_RESULT_FAILED_OTHER,
  HS_AUTHENTICATION_RESULT_MAX
} eHS_AUTHENTICATION_RESULT;
```

Constants

HS_AUTHENTICATION_RESULT_SUCCESS
Indicates the authentication was successful.

HS_AUTHENTICATION_RESULT_FAILED_TIMEOUT
Indicates the authentication failed due to a timeout from the server/back end.

HS_AUTHENTICATION_RESULT_FAILED_AUTH

Indicates the authentication failed due to incorrect credentials.

HS_AUTHENTICATION_RESULT_FAILED_CONNECT

Indicates the authentication failed due to an inability to connect to the authentication server

HS_AUTHENTICATION_RESULT_FAILED_OTHER

Indicates the authentication failed for some other reason.

HS_AUTHENTICATION_RESULT_MAX

Indicates an out-of-range value.

Remarks

The plugin passes this enumeration value to the hotspot plugin host through the HS_HOST_POST_CONNECT_AUTH_COMPLETION function, which is used to inform the hotspot plugin host of the results of a call to HS_PLUGIN_START_POST_CONNECT_AUTH.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

eHS_NETWORK_STATE enumeration

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **eHS_NETWORK_STATE** enumeration indicates whether a network is a hotspot network.

Syntax

ManagedCPlusPlus

```
typedef enum _eHS_NETWORK_STATE {
  HS_NETWORK_STATE_NOT_A_HOTSPOT,
  HS_NETWORK_STATE_HOTSPOT_MANUAL_CONNECT,
  HS_NETWORK_STATE_HOTSPOT_AUTO_CONNECT,
  HS_NETWORK_STATE_MAX
} eHS_NETWORK_STATE;
```

Constants

HS_NETWORK_STATE_NOT_A_HOTSPOT
Indicates the network is not a hotspot network.

HS_NETWORK_STATE_HOTSPOT_MANUAL_CONNECT
Indicates the user can manually connect to the hotspot network.

HS_NETWORK_STATE_HOTSPOT_AUTO_CONNECT
Indicates the device can connect automatically to the hotspot network.

HS_NETWORK_STATE_MAX

Indicates an out-of-range value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

eHS_UNLOAD_REASON enumeration

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

ⓘ **Important**

Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).

For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **eHS_UNLOAD_REASON** enumeration indicates the reason for the plugin to get unloaded.

Syntax

ManagedCPlusPlus

```
typedef enum _eHS_UNLOAD_REASON {
  HS_UNLOAD_REASON_NONE,
  HS_UNLOAD_REASON_PLUGN_INIT_FAILED,
  HS_UNLOAD_REASON_NO_NETWORKS_SUPPORTED,
  HS_UNLOAD_REASON_NO_PROVIDE_NAME_ID,
  HS_UNLOAD_REASON_ZERO_SIM_COUNT,
  HS_UNLOAD_REASON_DISPLAY_FLAG_BUT_NO_DISPLAY_STRING_ID,
  HS_UNLOAD_REASON_CUSTOM_REALM_FLAG_BUT_NO_REALM_STRING,
  HS_UNLOAD_REASON_DUPLICATE_PLUGIN_LOADED,
  HS_UNLOAD_REASON_RELOAD_REQUESTED_BY_PLUGIN,
  HS_UNLOAD_REASON_EXCEPTION_DURING_PLUGIN_CALL,
  HS_UNLOAD_REASON_EXCEPTION_IN_PLUGIN_HOST,
  HS_UNLOAD_REASON_ASYNC_INITIALIZATION_FAILED,
  HS_UNLOAD_REASON_UNSUPPORTED_AUTH_CAPABILITY_REQUESTED,
  HS_UNLOAD_REASON_FAILED_TO_LOAD_PROVIDER_NAME_STRING,
  HS_UNLOAD_REASON_FAILED_TO_LOAD_ADVANCED_PAGE_STRING,
  HS_UNLOAD_REASON_FAILED_TO_LOAD_NETWORK_NAME_STRING,
  HS_UNLOAD_REASON_FAILED_TO_CONFIGURE_HIDDEN_NETWORK,
  HS_UNLOAD_REASON_HIDDEN_NETWORK_ALREADY_CONFIGURED,
  HS_UNLOAD_REASON_FAILED_TO_QUERY_SIMS,
  HS_UNLOAD_REASON_PLUGIN_REQUIRED_SIM_NOT_PRESENT,
  HS_UNLOAD_REASON_SIM_CONFIG_CHANGED,
  HS_UNLOAD_REASON_WIFI_SWITCHED_OFF_IN_OS,
  HS_UNLOAD_REASON_MAX
} eHS_UNLOAD_REASON;
```

Constants

HS_UNLOAD_REASON_NONE
No specific reason for the unload operation.

HS_UNLOAD_REASON_PLUGN_INIT_FAILED
The plugin is being unloaded because it failed to initialize successfully.

HS_UNLOAD_REASON_NO_NETWORKS_SUPPORTED
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure did not indicate a valid value for **dwNumNetworksSupported**.

HS_UNLOAD_REASON_NO_PROVIDE_NAME_ID
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure did not specify a string ID for **dwProviderNameStringID**.

HS_UNLOAD_REASON_ZERO_SIM_COUNT
The plugin is being unloaded because there are no SIM cards present.

HS_UNLOAD_REASON_DISPLAY_FLAG_BUT_NO_DISPLAY_STRING_ID
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure requires HTTP or EAP SIM-based authentication but did not specify a value for **dwSupportedSIMCount.**

HS_UNLOAD_REASON_CUSTOM_REALM_FLAG_BUT_NO_REALM_STRING
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure specified the **HS_FLAG_CAPABILITY_NETWORK_CUSTOM_REALM** capability but did not provide a valid string for **szRealm**.

HS_UNLOAD_REASON_DUPLICATE_PLUGIN_LOADED
The plugin is being unloaded because another plugin is using the same DLL.

HS_UNLOAD_REASON_RELOAD_REQUESTED_BY_PLUGIN
The plugin is being unloaded because the plugin requested to be unloaded and reloaded by specifying the **HS_UPDATE_RESULT_ACTION_RELOAD** action with the eHS_UPDATE_RESULT enumeration.

HS_UNLOAD_REASON_EXCEPTION_DURING_PLUGIN_CALL
The plugin is being unloaded because the host process encountered an exception while in a call to the plugin.

HS_UNLOAD_REASON_EXCEPTION_IN_PLUGIN_HOST
The plugin is being unloaded because the hotspot host encountered an exception.

HS_UNLOAD_REASON_ASYNC_INITIALIZATION_FAILED
The plugin is being unloaded because the hotspot service failed to register for notifications from the plugin.

HS_UNLOAD_REASON_UNSUPPORTED_AUTH_CAPABILITY_REQUESTED
The plugin is being unloaded because none of the authentication capabilities requested by the plugin are available.

HS_UNLOAD_REASON_FAILED_TO_LOAD_PROVIDER_NAME_STRING
The plugin is being unloaded because the hotspot service could not map the **dwProviderNameStringID** string ID provided in the plugin's HS_PLUGIN_PROFILE structure to a valid string.

HS_UNLOAD_REASON_FAILED_TO_LOAD_ADVANCED_PAGE_STRING
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure specified an (optional) **dwAdvancedPageStringID** string ID but it did not map to a valid string.

HS_UNLOAD_REASON_FAILED_TO_LOAD_NETWORK_NAME_STRING
The plugin is being unloaded because the plugin's HS_PLUGIN_PROFILE structure specified an (optional) **dwGenericNetworkNameStringID** string ID, but it did not map to a valid string.

HS_UNLOAD_REASON_FAILED_TO_CONFIGURE_HIDDEN_NETWORK
The plugin is being unloaded because the plugin specified a hidden network (via the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability), but the hotspot service was unable to configure the hidden network.

HS_UNLOAD_REASON_HIDDEN_NETWORK_ALREADY_CONFIGURED
The plugin is being unloaded because the plugin specified a hidden network via the **HS_FLAG_CAPABILITY_NETWORK_TYPE_HIDDEN** capability but another plugin has already claimed the hidden network slot.

HS_UNLOAD_REASON_FAILED_TO_QUERY_SIMS
The plugin is being unloaded because the call to HS_PLUGIN_QUERY_SUPPORTED_SIMS failed.

HS_UNLOAD_REASON_PLUGIN_REQUIRED_SIM_NOT_PRESENT
The plugin is being unloaded because the SIMs required by the plugin are not present in the device.

HS_UNLOAD_REASON_SIM_CONFIG_CHANGED
The plugin is being unloaded because the SIM configuration changed, which requires the plugins to be unloaded and reloaded.

HS_UNLOAD_REASON_WIFI_SWITCHED_OFF_IN_OS
The plugin is being unloaded because Wi-Fi functionality was switched off in the OS.

HS_UNLOAD_REASON_MAX
Indicates an out-of-range value.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

HS_PLUGIN_PROFILE

eHS_UPDATE_RESULT

HS_PLUGIN_QUERY_SUPPORTED_SIMS

eHS_UPDATE_RESULT enumeration

Article • 03/03/2023

Wi-Fi Hotspot Offloading deprecation note

> ⓘ **Important**
>
> Starting in Windows 10, version 1709, the Wi-Fi Hotspot Offloading feature is deprecated and should not be used. Instead, we recommend writing a UWP app and using the Wi-Fi Hotspot Authentication API (Windows.Networking.NetworkOperators).
>
> For a code sample and more info, see the **Wi-Fi hotspot authentication sample**.

The **eHS_UPDATE_RESULT** enumeration indicates the result of a “check for updates” request.

Syntax

ManagedCPlusPlus

```
typedef enum _eHS_UPDATE_RESULT {
  HS_UPDATE_RESULT_SUCCESS,
  HS_UPDATE_RESULT_ACTION_RECONNECT,
  HS_UPDATE_RESULT_ACTION_RELOAD,
  HS_UPDATE_RESULT_MAX
} eHS_UPDATE_RESULT;
```

Constants

HS_UPDATE_RESULT_SUCCESS
Indicates the update was successful.

HS_UPDATE_RESULT_ACTION_RECONNECT
The result of the update request requires the service to disconnect and reconnect.

HS_UPDATE_RESULT_ACTION_RELOAD
The result of the update request requires the service to unload and reload the plugin.

HS_UPDATE_RESULT_MAX

Indicates an out-of-range value.

Remarks

The plugin passes this enumeration value to the hotspot plugin host through the HS_HOST_UPDATE_CONFIGURATION_COMPLETION function, which is used to inform the hotspot plugin host of the results of a call to HS_PLUGIN_CHECK_FOR_UPDATES.

Requirements

Version	Windows 10 Mobile
Header	Hotspotoffloadplugin.h (include Hotspotoffloadplugin.h)

Network Module Registrar Topics

Article • 12/15/2021

This section discusses the Network Module Registrar and includes the following topics:

Introduction to the Network Module Registrar

Network Module

Architecture Overview

Initializing and Registering a Client Module

Provider Module Operations

Programming Considerations

Using the **WskRegister** and **WskDeregister** functions is the preferred method for registering and unregistering WSK applications. The Network Module Registrar remains available for compatibility. For more information, see Registering a Winsock Kernel Application.

Introduction to the Network Module Registrar

Article • 12/15/2021

The Network Module Registrar (NMR) is an operating system module that facilitates the attachment of network modules to each other. Each network module registers itself with the NMR, specifying the characteristics that describe the network module. The NMR initiates attachment between pairs of registered network modules that can be attached to each other. After they are attached, the network modules can interact with each other independent of the NMR. The NMR also facilitates detachment of attached pairs of network modules when one of the network modules deregisters with the NMR. The deregistration of a network module is not complete until the network module is completely detached from all network modules to which it was previously attached.

Although the NMR was developed for use by network modules, the design of the NMR architecture is sufficiently generic so that it can also be used by software modules in other technology areas.

Network Module

Article • 12/15/2021

A *network module* is a software module that implements a specific function in a network stack, such as a data link interface, a transport protocol, or a network application. A network module can be a provider module, a client module, or both, depending on where it is located in the network stack.

Provider Module

Article • 12/15/2021

A *provider module* is a network module that supports and implements the provider side of a Network Programming Interface (NPI). A provider module registers itself with the Network Module Registrar as a *Provider* of the NPI that it supports. A provider module can register itself as a provider of more than one NPI. A network module can be both a provider module and a client module.

Client Module

Article • 12/15/2021

A *client module* is a network module that supports and implements the client side of a Network Programming Interface (NPI). A client module registers itself with the Network Module Registrar as a *Client* of the NPI that it supports. A client module can register itself as a client of more than one NPI. A network module can be both a client module and a provider module.

Network Programming Interface

Article • 12/15/2021

A *Network Programming Interface*, or NPI, defines the interface between network modules that can be attached to one another. A client module that is registered as a client of a particular NPI can only be attached to provider modules that are registered as providers of the same NPI. Likewise, a provider module that is registered as a provider of a particular NPI can only be attached to client modules that are registered as clients of the same NPI.

Each NPI defines the following items:

- An *NPI identifier* that uniquely identifies the NPI. A network module specifies an NPI identifier to indicate the particular NPI that it supports when the network module registers itself with the Network Module Registrar (NMR). A network module can support multiple NPIs by registering itself with the NMR multiple times, once for each NPI that it supports. The NMR will initiate attaching a client module to a provider module only if they both support the same NPI.

- An optional *client characteristics* structure that specifies the NPI-specific characteristics of each client module. Such NPI-specific characteristics might include items such as which version (or versions) of the NPI that a client module supports, or which address family or protocol a client module requires. A provider module can use the information contained in a client module's client characteristics structure to determine if it will attach to the client module. If an NPI does not define any NPI-specific client characteristics, then this structure is not required.

- An optional *provider characteristics* structure that specifies the NPI-specific characteristics of each provider module. Such NPI-specific characteristics might include items such as which version (or versions) of the NPI that a provider module supports, or which address families or protocols a provider module supports. A client module can use the information contained in a provider module's client characteristics structure to determine if it will attach to the provider module. If an NPI does not define any NPI-specific provider characteristics, then this structure is not required.

- Zero or more client module callback functions. After a provider module successfully attaches to a client module, the provider module can access the client module's functionality by calling the client module's callback functions.

- One or more provider module functions. After a client module successfully attaches to a provider module, the client module can access the provider module's functionality by calling the provider module's functions.
- A *client dispatch table* structure that contains function pointers to each of the client module callback functions. If an NPI does not define any client module callback functions, then this structure is not required.
- A *provider dispatch table* structure that contains function pointers to each of the provider module functions.

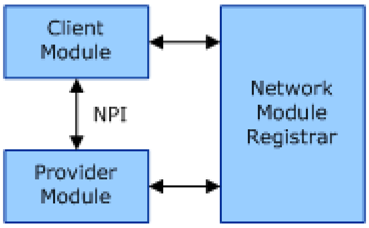
A client module that supports a particular NPI uses the items defined by the NPI to implement the client side of the interface. Similarly, a provider module that supports a particular NPI uses the items defined by the NPI to implement the provider side of the interface.

All of the items defined by an NPI are opaque to the NMR except for the NPI identifier. The NMR uses the NPI identifier to determine which client modules should be attached to which provider modules.

Architecture overview for the Network Module Registrar

Article • 12/15/2021

An overview of the basic architecture of the Network Module Registrar (NMR) is shown in the following diagram:



In this situation, there are two network modules, a client module and a provider module. The client module and the provider module are respectively a client and a provider of the same Network Programming Interface (NPI). Each network module interacts directly with the NMR for the purpose of registration and deregistration, as well as attaching to, and detaching from, other network modules. The NMR will initiate attaching a client module to a provider module only if they both support the same NPI. After the client module and the provider module are attached to each other, they can interact with each other through their NPI functions independent of the NMR.

The following sections provide an overview of the process by which a client module and a provider module that both support a common NPI are attached and detached.

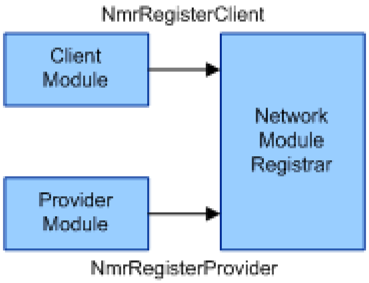
Network Module Attachment

Network Module Detachment

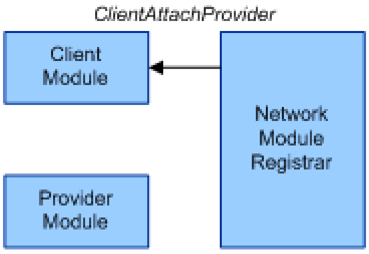
Network Module Attachment

Article • 12/15/2021

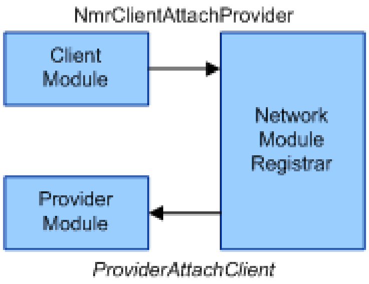
Before a client module and a provider module can be attached to one another, they each must register themselves with the NMR. A client module registers with the NMR by calling the **NmrRegisterClient** function and a provider module registers with the NMR by calling the **NmrRegisterProvider** function. The following diagram illustrates network module registration.



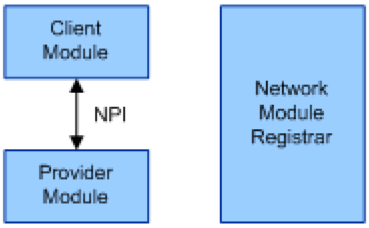
If the client module and the provider module both specify the same Network Programming Interface (NPI) when they register with the NMR, the NMR will initiate attaching the two network modules together. The NMR initiates the attachment process by calling the client module's *ClientAttachProvider* callback function. The following diagram illustrates the Network Module Registrar (NMR) initiating the attachment.



A client module's *ClientAttachProvider* callback function can examine the registration data for the provider module to determine if it will attach to the provider module. If the client module determines that it will attach to the provider module, it continues the attachment process by calling the **NmrClientAttachProvider** function. When a client module calls the **NmrClientAttachProvider** function, the NMR in turn calls the provider module's *ProviderAttachClient* callback function. The following diagram illustrates the client module continuing the attachment.



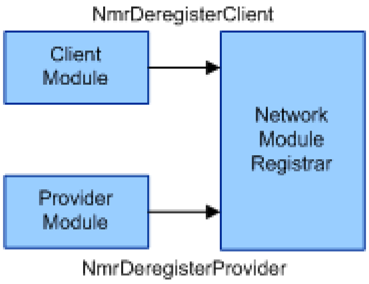
A provider module's *ProviderAttachClient* callback function can examine the registration data for the client module to determine if it will attach to the client module. If the provider module determines that it will attach to the client module, the provider module and client module exchange pointers to their respective NPI dispatch table structures. After the client module and provider module are attached, they can interact with each other through their NPI functions independent of the NMR. The following diagram illustrates the network modules attached.



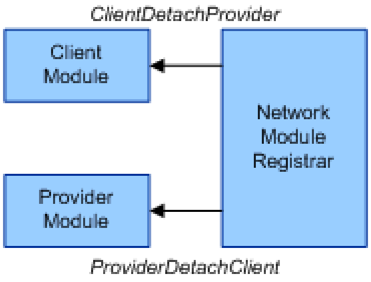
Network Module Detachment

Article • 12/15/2021

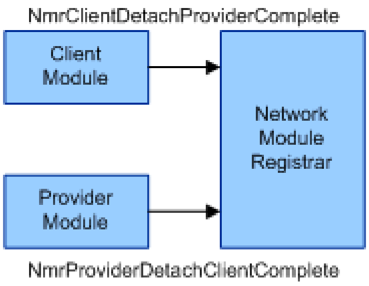
An attached pair of network modules are detached from each other when either the client module or the provider module deregisters with the Network Module Registrar (NMR). A client module deregisters with the NMR by calling the **NmrDeregisterClient** function and a provider module deregisters with the NMR by calling the **NmrDeregisterProvider** function. The following diagram illustrates the network modules initiating deregistration.



When either network module deregisters with the NMR, the NMR calls both the client module's *ClientDetachProvider* callback function and the provider module's *ProviderDetachClient* callback function to initiate detaching the network module. The following diagram illustrates the NMR initiating the detachment.

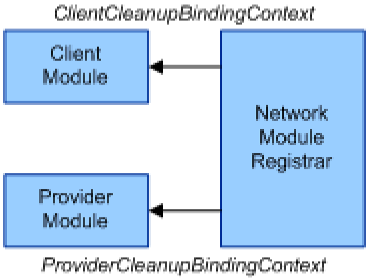


If the client module is unable to detach itself from the provider module immediately, it calls the **NmrClientDetachProviderComplete** function after it completes detaching itself from the provider module. Likewise, if the provider module cannot detach itself from the client module immediately, it calls the **NmrProviderDetachClientComplete** function after it completes detaching itself from the client module. The following diagram illustrates the network modules completing the detachment.

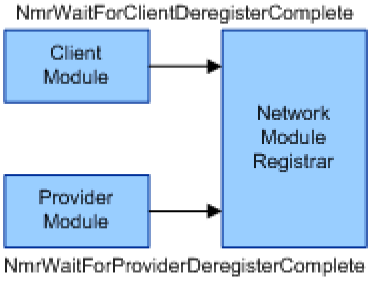


NmrClientDetachProviderComplete
Client Module
Network Module Registrar
Provider Module
NmrProviderDetachClientComplete

After both the client module and the provider module have completed detachment from each other, the NMR calls the client module's *ClientCleanupBindingContext* callback function and the provider module's *ProviderCleanupBindingContext* callback function so that the network modules can clean up their respective binding contexts for the attachment. The following diagram illustrates the NMR initiating cleanup.



If the client module deregistered with the NMR, the deregistration of the client module is not complete until the client module has completely detached from all of the provider modules that it was previously attached to and all of those provider modules have completely detached from the client module. The client module waits for the deregistration to complete by calling the **NmrWaitForClientDeregisterComplete** function. Likewise, if the provider module deregistered with the NMR, the deregistration of the provider module is not complete until the provider module has completely detached from all of the client modules that it was previously attached to and all of those client modules have completely detached from the provider module. The provider module waits for the deregistration to complete by calling the **NmrWaitForProviderDeregisterComplete** function. The following diagram illustrates the network modules waiting for deregistration to complete.



NmrWaitForClientDeregisterComplete
Client Module
Network Module Registrar
Provider Module
NmrWaitForProviderDeregisterComplete

Initializing and Registering a Client Module

Article • 12/15/2021

A client module must initialize a number of data structures before it can register itself with the Network Module Registrar (NMR). These structures include an **NPI_MODULEID** structure, an **NPI_CLIENT_CHARACTERISTICS** structure, an **NPI_REGISTRATION_INSTANCE** structure (contained within the NPI_CLIENT_CHARACTERISTICS structure), and a structure defined by the client module that is used for the client module's registration context.

If a client module registers itself with the NMR as a client of a Network Programming Interface (NPI) that defines NPI-specific client characteristics, the client module must also initialize an instance of the client characteristics structure defined by the NPI.

All of these data structures must remain valid and resident in memory as long as the client module is registered with the NMR.

For example, suppose the "EXNPI" NPI defines the following in header file Exnpi.h:

C++

```
// EXNPI NPI identifier
const NPIID EXNPI_NPIID = { ... };

// EXNPI client characteristics structure
typedef struct EXNPI_CLIENT_CHARACTERISTICS_
{
  .
  . // NPI-specific members
  .
} EXNPI_CLIENT_CHARACTERISTICS, *PEXNPI_CLIENT_CHARACTERISTICS;
```

The following shows how a client module that registers itself as a client of the EXNPI NPI can initialize all of these data structures:

C++

```
// Include the NPI specific header file
#include "exnpi.h"

// Structure for the client module's NPI-specific characteristics
const EXNPI_CLIENT_CHARACTERISTICS NpiSpecificCharacteristics =
{
  .
  . // The NPI-specific characteristics of the client module
  .
};

// Structure for the client module's identification
const NPI_MODULEID ClientModuleId =
{
  sizeof(NPI_MODULEID),
  MIT_GUID,
  { ... }  // A GUID that uniquely identifies the client module
};

// Prototypes for the client module's callback functions
NTSTATUS
  ClientAttachProvider(
    IN HANDLE NmrBindingHandle,
    IN PVOID ClientContext,
    IN PNPI_REGISTRATION_INSTANCE ProviderRegistrationInstance
    );

NTSTATUS
  ClientDetachProvider(
    IN PVOID ClientBindingContext
    );

VOID
  ClientCleanupBindingContext(
    IN PVOID ClientBindingContext
    );

// Structure for the client module's characteristics
const NPI_CLIENT_CHARACTERISTICS ClientCharacteristics =
{
  0,
  sizeof(NPI_CLIENT_CHARACTERISTICS),
  ClientAttachProvider,
  ClientDetachProvider,
  ClientCleanupBindingContext,
  {
    0,
    sizeof(NPI_REGISTRATION_INSTANCE),
    &EXNPI_NPIID,
    &ClientModuleId,
    0,
    &NpiSpecificCharacteristics
  }
};

// Context structure for the client module's registration
typedef struct CLIENT_REGISTRATION_CONTEXT_ {
  .
  . // Client-specific members
  .
} CLIENT_REGISTRATION_CONTEXT, *PCLIENT_REGISTRATION_CONTEXT;
```

```
// Structure for the client's registration context
CLIENT_REGISTRATION_CONTEXT ClientRegistrationContext =
{
  .
  . // Initial values for the registration context
  .
};
```

A client module typically initializes itself within its **DriverEntry** function. The main initialization tasks for a client module are:

- Specify an **Unload** function. The operating system calls this function when the client module is unloaded from the system. If a client module does not provide an unload function, the client module cannot be unloaded from the system.

- Call the **NmrRegisterClient** function to register the client module with the NMR.

For example:

C++

```
// Prototype for the client module's unload function
VOID
  Unload(
    PDRIVER_OBJECT DriverObject
    );

// Variable to contain the handle for the registration
HANDLE ClientHandle;

// DriverEntry function
NTSTATUS
  DriverEntry(
    PDRIVER_OBJECT DriverObject,
    PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS Status;

  // Specify the unload function
  DriverObject->DriverUnload = Unload;

  .
  . // Other initialization tasks
  .

  // Register the client module with the NMR
  Status = NmrRegisterClient(
    &ClientCharacteristics,
    &ClientRegistrationContext,
    &ClientHandle
    );
  // Return the result of the registration
  return Status;
}
```

If a client module is a client of more than one NPI, it must initialize an independent set of data structures and call **NmrRegisterClient** for each NPI that it supports. If a network module is both a client module and a provider module (that is, it is a client of one NPI and a provider of another NPI), it must initialize two independent sets of data structures, one for the client interface and one for the provider interface, and call both **NmrRegisterClient** and **NmrRegisterProvider**.

A client module is not required to call **NmrRegisterClient** from within its **DriverEntry** function. For example, in the situation where a client module is a subcomponent of a complex driver, the registration of the client module might occur only when the client module subcomponent is activated.

For more information about implementing a client module's **Unload** function, see Unloading a Client Module.

Attaching a Client Module to a Provider Module

Article • 12/15/2021

After a client module has registered with the Network Module Registrar (NMR), the NMR calls the client module's *ClientAttachProvider* callback function, once for each provider module that is registered as a provider of the same Network Programming Interface (NPI) for which the client module has registered as a client.

The NMR also calls a client module's *ClientAttachProvider* callback function whenever a new provider module registers as a provider of the same NPI for which the client module has registered as a client.

When the NMR calls the client module's *ClientAttachProvider* callback function for a particular provider module, it passes, in the *ProviderRegistrationInstance* parameter, a pointer to the **NPI_REGISTRATION_INSTANCE** structure that is associated with the provider module. The client module's *ClientAttachProvider* callback function can use the data in the provider module's **NPI_REGISTRATION_INSTANCE** structure, as well as the data in the **NPI_MODULEID** structure and the NPI-specific provider characteristics structure pointed to by the **ModuleId** and **NpiSpecificCharacteristics** members of the provider module's **NPI_REGISTRATION_INSTANCE** structure, to determine if it will attach to the provider module.

If the client module determines that it will attach to the provider module, the client module's *ClientAttachProvider* callback function allocates and initializes a binding context structure for the attachment to the provider module and then calls the **NmrClientAttachProvider** function to continue the attachment process. In this situation, the client module's *ClientAttachProvider* callback function must return the status code that is returned by the **NmrClientAttachProvider** function.

If **NmrClientAttachProvider** returns STATUS_SUCCESS, the client module and the provider module have successfully attached to each other. In this situation, the client module's *ClientAttachProvider* callback function must save the binding handle that the NMR passed in the *NmrBindingHandle* parameter when the NMR called the client module's *ClientAttachProvider* callback function. The client module's *ClientAttachProvider* callback function must also save the pointers to the provider binding context and the provider dispatch table that are returned in the variables that the client module passed to the **NmrClientAttachProvider** function in the *ProviderBindingContext* and *ProviderDispatch* parameters. A client module typically saves this data in its binding context for the attachment to the provider module.

If **NmrClientAttachProvider** does not return STATUS_SUCCESS, the client module's *ClientAttachProvider* callback function should clean up and free any resources that it allocated before it called **NmrClientAttachProvider**.

If the client module determines that it will not attach to the provider module, then the client module's *ClientAttachProvider* callback function must return STATUS_NOINTERFACE.

For example, suppose the "EXNPI" Network Programming Interface (NPI) defines the following in header file Exnpi.h:

C++

```
// EXNPI provider characteristics structure
typedef struct EXNPI_PROVIDER_CHARACTERISTICS_
{
  .
  . // NPI-specific members
  .
} EXNPI_PROVIDER_CHARACTERISTICS, *PEXNPI_PROVIDER_CHARACTERISTICS;

// EXNPI client dispatch table
typedef struct EXNPI_CLIENT_DISPATCH_ {
  .
  . // NPI-specific dispatch table of function pointers that
  . // point to a client module's NPI callback functions.
  .
} EXNPI_CLIENT_DISPATCH, *PEXNPI_CLIENT_DISPATCH;

// EXNPI provider dispatch table
typedef struct EXNPI_PROVIDER_DISPATCH_ {
  .
  . // NPI-specific dispatch table of function pointers that
  . // point to a provider module's NPI functions.
  .
} EXNPI_PROVIDER_DISPATCH, *PEXNPI_PROVIDER_DISPATCH;
```

The following code example shows how a client module that is registered as a client of the EXNPI NPI can attach itself to a provider module that is registered as a provider of the EXNPI NPI:

C++

```
// Context structure for the client
// module's binding to a provider module
typedef struct CLIENT_BINDING_CONTEXT_ {
  HANDLE NmrBindingHandle;
  PVOID ProviderBindingContext;
  PEXNPI_PROVIDER_DISPATCH ProviderDispatch;
  .
  . // Other client-specific members
  .
} CLIENT_BINDING_CONTEXT, *PCLIENT_BINDING_CONTEXT;

// Pool tag used for allocating the binding context
#define BINDING_CONTEXT_POOL_TAG 'tpcb'

// Structure for the client's dispatch table
const EXNPI_CLIENT_DISPATCH Dispatch = {
  .
  . // Function pointers to the client module's
  . // NPI callback functions
  .
};

// ClientAttachProvider callback function
NTSTATUS
  ClientAttachProvider(
    IN HANDLE NmrBindingHandle,
    IN PVOID ClientContext,

      );
  }

  // Return result of attachment
  return Status;
}
```

Managing Multiple Attached Provider Modules

Article • 05/03/2023

A single client module can attach to more than one provider module. In order to manage multiple attached provider modules, a client module must independently save the binding handle, the provider module's binding context, and the provider module's dispatch table for each provider module to which it is attached. Typically this data is saved in the client module's binding context for each attachment. However, a client module can manage the data for each attached provider module in whatever way it chooses.

A Network Programming Interface (NPI) typically defines the client module callback functions such that they include either a pointer to the client module's binding context or some other NPI-specific identifier as one of the function parameters. As a result, a client module can determine which provider module is the caller when one of its NPI callback functions is called.

Detaching a Client Module from a Provider Module

Article • 12/15/2021

When a client module deregisters with the Network Module Registrar (NMR) by calling the **NmrDeregisterClient** function, the NMR calls the client module's *ClientDetachProvider* callback function, once for each provider module to which it is attached, so that the client module can detach itself from all of the provider modules as part of the client module's deregistration process.

Furthermore, whenever a provider module to which the client module is attached deregisters with the NMR by calling the **NmrDeregisterProvider** function, the NMR also calls the client module's *ClientDetachProvider* callback function so that the client module can detach itself from the provider module as part of the provider module's deregistration process.

After its *ClientDetachProvider* callback function has been called, a client module must not make any further calls to any of the provider module's Network Programming Interface (NPI) functions. If there are no in-progress calls to any of the provider module's NPI functions when the client module's *ClientDetachProvider* callback function is called, then the *ClientDetachProvider* callback function should return STATUS_SUCCESS.

If there are in-progress calls to one or more of the provider module's NPI functions when the client module's *ClientDetachProvider* callback function is called, then the *ClientDetachProvider* callback function should return STATUS_PENDING. In this case, the client module must call the **NmrClientDetachProviderComplete** function after all in-progress calls to the provider module's NPI functions have completed. The call to **NmrClientDetachProviderComplete** notifies the NMR that detachment of the client module from the provider module is complete.

For more information about how to track the number of in-progress calls to a provider module's NPI functions, see Programming Considerations.

If a client module implements a *ClientCleanupBindingContext* callback function, the NMR calls the client module's *ClientCleanupBindingContext* callback function after both the client module and the provider module have completed detachment from each other. A client module's *ClientCleanupBindingContext* callback function should perform any necessary cleanup of the data contained within the client module's binding context structure. It should then free the memory for the binding context structure if the client module dynamically allocated the memory for the structure.

For example:

C++

```cpp
// ClientDetachProvider callback function
NTSTATUS
  ClientDetachProvider(
    IN PVOID ClientBindingContext
    )
{
  PCLIENT_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext = (PCLIENT_BINDING_CONTEXT)ClientBindingContext;

  // Set a flag indicating that the client module is detaching
  // from the provider module so that no more calls are made to
  // the provider module's NPI functions.
  ...

  // Check if there are no in-progress NPI function calls to the
  // provider module
  if (...)
  {
    // Return success status indicating detachment is complete
    return STATUS_SUCCESS;
  }

  // There are one or more in-progress NPI function calls
  // to the provider module
  else
  {
    // Return pending status indicating detachment is pending
    // completion of the in-progress NPI function calls
    return STATUS_PENDING;

    // When the last in-progress call to the provider module's
    // NPI functions completes, the client module must call
    // NmrClientDetachProviderComplete() with the binding handle
    // for the attachment to the provider module.
  }
}

// ClientCleanupBindingContext callback function
VOID
  ClientCleanupBindingContext(
    IN PVOID ClientBindingContext
    )
{
  PCLIENT_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext = (PCLIENT_BINDING_CONTEXT)ClientBindingContext;
  // Clean up the client binding context structure
  ...

  // Free the memory for client's binding context structure
  ExFreePoolWithTag(
    BindingContext,
    BINDING_CONTEXT_POOL_TAG
    );
}
```

Unloading a Client Module

Article • 12/15/2021

To unload a client module, the operating system calls the client module's **Unload** function. See Initializing and Registering a Client Module for more information about how to specify a client module's **Unload** function during initialization.

A client module's **Unload** function ensures that the client module is deregistered from the Network Module Registrar (NMR) before the client module is unloaded from system memory. A client module initiates deregistration from the NMR by calling the NmrDeregisterClient function, which it typically calls from its **Unload** function. A client module must not return from its **Unload** function until after it has been completely deregistered from the NMR. If the call to **NmrDeregisterClient** returns STATUS_PENDING, the client module must call the NmrWaitForClientDeregisterComplete function to wait for the deregistration to complete before it returns from its **Unload** function.

For example:

C++

```
// Variable containing the handle for the registration
HANDLE ClientHandle;

// Unload function
VOID
  Unload(
    IN PDRIVER_OBJECT DriverObject
    )
{
  NTSTATUS Status;

  // Deregister the client module from the NMR
  Status =
    NmrDeregisterClient(
      ClientHandle
      );

  // Check if pending
  if (Status == STATUS_PENDING)
  {
    // Wait for the deregistration to be completed
    NmrWaitForClientDeregisterComplete(
      ClientHandle
      );
  }

  // An error occurred
```

```
    else
    {
      // Handle error
      ...
    }
  }
```

If a client module is registered as a client of multiple Network Programming Interfaces (NPIs), it must call **NmrDeregisterClient** for each NPI that it supports. If a network module is registered as both a client module and a provider module (that is, it is a client of one NPI and a provider of another NPI), it must call both **NmrDeregisterClient** and **NmrDeregisterProvider**.

A network module must wait until all of the deregistrations are complete before returning from its **Unload** function.

A client module is not required to call **NmrDeregisterClient** from within its **Unload** function. For example, in the situation where a client module is a subcomponent of a complex driver, the deregistration of the client module might occur when the client module subcomponent is deactivated. However, in such a situation the driver must still ensure that the client module has been completely deregistered from the NMR before returning from its **Unload** function.

Initializing and Registering a Provider Module

Article • 12/15/2021

A provider module must initialize a number of data structures before it can register itself with the Network Module Registrar (NMR). These structures include an NPI_MODULEID structure, an NPI_PROVIDER_CHARACTERISTICS structure, an NPI_REGISTRATION_INSTANCE structure (contained within the NPI_PROVIDER_CHARACTERISTICS structure), and a structure defined by the provider module that is used for the provider module's registration context.

If a provider module registers itself with the NMR as a provider of a Network Programming Interface (NPI) that defines NPI-specific provider characteristics, the provider module must also initialize an instance of the provider characteristics structure that are defined by the NPI.

All of these data structures must remain valid and resident in memory as long as the provider module is registered with the NMR.

For example, suppose the "EXNPI" NPI defines the following in header file Exnpi.h:

C++

```
// EXNPI NPI identifier
const NPIID EXNPI_NPIID = { ... };

// EXNPI provider characteristics structure
typedef struct EXNPI_PROVIDER_CHARACTERISTICS_
{
  .
  . // NPI-specific members
  .
} EXNPI_PROVIDER_CHARACTERISTICS, *PEXNPI_PROVIDER_CHARACTERISTICS;
```

The following shows how a provider module that registers itself as a provider of the EXNPI NPI can initialize all of these data structures:

C++

```
// Include the NPI specific header file
#include "exnpi.h"

// Structure for the provider module's NPI-specific characteristics
const EXNPI_PROVIDER_CHARACTERISTICS NpiSpecificCharacteristics =
{
  .
  . // The NPI-specific characteristics of the provider module
  .
};

// Structure for the provider module's identification
const NPI_MODULEID ProviderModuleId =
{
  sizeof(NPI_MODULEID),
  MIT_GUID,
  { ... }  // A GUID that uniquely identifies the provider module
};

// Prototypes for the provider module's callback functions
NTSTATUS
  ProviderAttachClient(
    IN HANDLE NmrBindingHandle,
    IN PVOID ProviderContext,
    IN PNPI_REGISTRATION_INSTANCE ClientRegistrationInstance,
    IN PVOID ClientBindingContext,
    IN CONST VOID *ClientDispatch,
    OUT PVOID *ProviderBindingContext,
    OUT PVOID *ProviderDispatch
    );

NTSTATUS
  ProviderDetachClient(
    IN PVOID ProviderBindingContext
    );

VOID
  ProviderCleanupBindingContext(
    IN PVOID ProviderBindingContext
    );

// Structure for the provider module's characteristics
const NPI_PROVIDER_CHARACTERISTICS ProviderCharacteristics =
{
  0,
  sizeof(NPI_PROVIDER_CHARACTERISTICS),
  ProviderAttachClient,
  ProviderDetachClient,
  ProviderCleanupBindingContext,
  {
    0,
    sizeof(NPI_REGISTRATION_INSTANCE),
    &EXNPI_NPIID,
    &ProviderModuleId,
    0,
    &NpiSpecificCharacteristics
  }
};

// Context structure for the provider module's registration
typedef struct PROVIDER_REGISTRATION_CONTEXT_ {
  .
  . // Provider-specific members
  .
} PROVIDER_REGISTRATION_CONTEXT, *PPROVIDER_REGISTRATION_CONTEXT;

// Structure for the provider's registration context
PROVIDER_REGISTRATION_CONTEXT ProviderRegistrationContext =
{
  .
  . // Initial values for the registration context
  .
};
```

A provider module typically initializes itself within its DriverEntry function. The main initialization tasks for a provider module are:

- Specify an Unload function. The operating system calls this function when the provider module is unloaded from the system. If a provider module does not provide an unload function, the provider module cannot be unloaded from the system.
- Call the NmrRegisterProvider function to register the provider module with the NMR.

For example:

C++

```
// Prototype for the provider module's unload function
VOID
  Unload(
    PDRIVER_OBJECT DriverObject
   );

// Variable to contain the handle for the registration
HANDLE ProviderHandle;

// DriverEntry function
NTSTATUS
  DriverEntry(
    PDRIVER_OBJECT DriverObject,
    PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS Status;

  // Specify the unload function
  DriverObject->DriverUnload = Unload;

  .
  . // Other initialization tasks
```

```
    .

    // Register the provider module with the NMR
    Status = NmrRegisterProvider(
      &ProviderCharacteristics,
      &ProviderRegistrationContext,
      &ProviderHandle
      );

    // Return the result of the registration
    return Status;
  }
```

If a provider module is a provider of more than one NPI, it must initialize an independent set of data structures and call **NmrRegisterProvider** for each NPI that it supports. If a network module is both a provider module and a client module (that is, it is a provider of one NPI and a client of another NPI), it must initialize two independent sets of data structures, one for the provider interface and one for the client interface, and call both **NmrRegisterProvider** and **NmrRegisterClient**.

A provider module is not required to call **NmrRegisterProvider** from within its **DriverEntry** function. For example, in the situation where a provider module is a subcomponent of a complex driver, the registration of the provider module might occur only when the provider module subcomponent is activated.

For more information about implementing a provider module's **Unload** function, see Unloading a Provider Module.

Attaching a Provider Module to a Client Module

Article • 12/15/2021

A client module calls the **NmrClientAttachProvider** function to attach itself to a provider module. For more information about how a client module attaches to a provider module, see Attaching a Client Module to a Provider Module.

When a client module calls **NmrClientAttachProvider**, the NMR calls the provider module's *ProviderAttachClient* callback function. When the NMR calls a provider module's *ProviderAttachClient* callback function, it passes, in the *ClientRegistrationInstance* parameter, a pointer to the **NPI_REGISTRATION_INSTANCE** structure that is associated with the client module that called **NmrClientAttachProvider**. The provider module's *ProviderAttachClient* callback function can use the data in the client module's **NPI_REGISTRATION_INSTANCE** structure, the data in the **NPI_MODULEID** structure and the Network Programming Interface (NPI)-specific client characteristics structure pointed to by the **ModuleId** and **NpiSpecificCharacteristics** members of the client module's **NPI_REGISTRATION_INSTANCE** structure, to determine if it will attach to the client module.

If the provider module determines that it will attach to the client module, then the provider module's *ProviderAttachClient* callback function must do the following:

- Allocate and initialize a binding context structure for the attachment to the client module.

- Save the binding handle passed in the *NmrBindingHandle* parameter.

- Save the pointers passed in the *ClientBindingContext* and *ClientDispatch* parameters so that the provider module can make calls to the client module's NPI callback functions.

- Set the variable pointed to by the *ProviderBindingContext* parameter to point to the provider module's binding context structure.

- Set the variable pointed to by the *ProviderDispatch* parameter to point to a structure that contains the provider module's dispatch table of NPI functions.

- Return STATUS_SUCCESS.

A provider module typically saves the binding handle, the pointer to the client binding context, and the pointer to the client dispatch structure in its binding context for the attachment to the client module.

If a provider module's *ProviderAttachClient* callback function returns STATUS_SUCCESS, the client module and the provider module have successfully attached to each other.

If the provider module determines that it will not attach to the client module, then the provider module's *ProviderAttachClient* callback function must return STATUS_NOINTERFACE.

For example, suppose the "EXNPI" Network Programming Interface (NPI) defines the following in header file Exnpi.h:

C++

```cpp
// EXNPI client characteristics structure
typedef struct EXNPI_CLIENT_CHARACTERISTICS_
{
  .
  . // NPI-specific members
  .
} EXNPI_CLIENT_CHARACTERISTICS, *PEXNPI_CLIENT_CHARACTERISTICS;

// EXNPI client dispatch table
typedef struct EXNPI_CLIENT_DISPATCH_ {
  .
  . // NPI-specific dispatch table of function pointers that
  . // point to a client module's NPI callback functions.
  .
} EXNPI_CLIENT_DISPATCH, *PEXNPI_CLIENT_DISPATCH;

// EXNPI provider dispatch table
typedef struct EXNPI_PROVIDER_DISPATCH_ {
  .
  . // NPI-specific dispatch table of function pointers that
  . // point to a provider module's NPI functions.
  .
} EXNPI_PROVIDER_DISPATCH, *PEXNPI_PROVIDER_DISPATCH;
```

The following code example shows how a provider module that is registered as a provider of the EXNPI NPI can attach itself to a client module that is registered as a client of the EXNPI NPI:

C++

```cpp
// Context structure for the provider
// module's binding to a client module
typedef struct PROVIDER_BINDING_CONTEXT_ {
  HANDLE NmrBindingHandle;
  PVOID ClientBindingContext;
  PEXNPI_CLIENT_DISPATCH ClientDispatch;
  .
  . // Other provider-specific members
  .
} PROVIDER_BINDING_CONTEXT, *PPROVIDER_BINDING_CONTEXT;

// Pool tag used for allocating the binding context
#define BINDING_CONTEXT_POOL_TAG 'tpcb'

// Structure for the provider's dispatch table
const EXNPI_PROVIDER_DISPATCH Dispatch = {
  .
  . // Function pointers to the provider
  . // module's NPI functions
  .
};

// ProviderAttachClient callback function
NTSTATUS
  ProviderAttachClient(
    IN HANDLE NmrBindingHandle,
    IN PVOID ProviderContext,
    IN PNPI_REGISTRATION_INSTANCE ClientRegistrationInstance,
    IN PVOID ClientBindingContext,
    IN CONST VOID *ClientDispatch,
    OUT PVOID *ProviderBindingContext,
    OUT PVOID *ProviderDispatch
    )
{
  PNPI_MODULEID ClientModuleId;
  PEXNPI_CLIENT_CHARACTERISTICS ClientNpiSpecificCharacteristics;
  PPROVIDER_BINDING_CONTEXT BindingContext;
  PVOID ClientBindingContext;
  PEXNPI_CLIENT_DISPATCH ClientDispatch;

  // Check parameters
  if ((ProviderBindingContext == NULL) ||
      (ProviderDispatch == NULL))
  {
    // Return error status code
    return STATUS_INVALID_PARAMETER;
  }

  // Get pointers to the client module's identification structure
  // and the client module's NPI-specific characteristics structure
  ClientModuleId = ClientRegistrationInstance->ModuleId;
  ClientNpiSpecificCharacteristics =
    (PEXNPI_CLIENT_CHARACTERISTICS)
      ProviderRegistrationInstance->NpiSpecificCharacteristics;

  //
  // Use the data in the structures pointed to by
  // ClientRegistrationInstance, ClientModuleId,
  // and ClientNpiSpecificCharacteristics to determine
  // whether to attach to the client module.
  //
  // If the provider module determines that it will not attach
  // to the client module
  if (...)
  {
    // Return status code indicating the modules did not
    // attach to each other
    return STATUS_NOINTERFACE;
  }

  // Allocate memory for the provider module's
  // binding context structure
  BindingContext =
    (PPROVIDER_BINDING_CONTEXT)
      ExAllocatePoolWithTag(
        NonPagedPool,
        sizeof(PROVIDER_BINDING_CONTEXT),
        BINDING_CONTEXT_POOL_TAG
        );

  // Check result of allocation
  if (BindingContext == NULL)
  {
    // Return error status code
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Initialize the provider binding context structure
  ...

  // Save NmrBindingHandle, ClientBindingContext,
  // and ClientDispatch for future reference
  BindingContext->NmrBindingHandle =
    NmrBindingHandle;
  BindingContext->ClientBindingContext =
    ClientBindingContext;
  BindingContext->ClientDispatch =
    ClientDispatch;

  // Return a pointer to the provider binding context structure
  // in the ProviderBindingContext parameter
  *ProviderBindingContext = BindingContext;

  // Return a pointer to the provider dispatch structure
  // in the ProviderDispatch parameter
  *ProviderDispatch = &Dispatch;

  // Return success status
  return STATUS_SUCCESS;
}
```

Managing Multiple Attached Client Modules

Article • 12/15/2021

A single provider module can attach to more than one client module. In order to manage multiple attached client modules, a provider module must independently save the binding handle, the client module's binding context, and the client module's dispatch table for each client module to which it is attached. Typically this data is saved in the provider module's binding context for each attachment. However, a provider module can manage the data for each attached client module in whatever way it chooses.

A Network Programming Interface (NPI) typically defines the provider module functions such that they include either a pointer to the provider module's binding context or some other NPI-specific identifier as one of the function parameters. As a result, a provider module can determine which client module is the caller when one of it's NPI functions is called.

Detaching a Provider Module from a Client Module

Article • 12/15/2021

When a provider module deregisters with the Network Module Registrar (NMR) by calling the **NmrDeregisterProvider** function, the NMR calls the provider module's *ProviderDetachClient* callback function, once for each client module to which it is attached, so that the provider module can detach itself from all of the client modules as part of the provider module's deregistration process.

Furthermore, whenever a client module to which the provider module is attached deregisters with the NMR by calling the **NmrDeregisterClient** function, the NMR also calls the provider module's *ProviderDetachClient* callback function so that the provider module can detach itself from the client module as part of the client module's deregistration process.

After its *ProviderDetachClient* callback function has been called, a provider module must not make any further calls to any of the client module's Network Programming Interface (NPI) callback functions. If there are no in-progress calls to any of the client module's NPI callback functions when the provider module's *ProviderDetachClient* callback function is called, then the *ProviderDetachClient* callback function should return STATUS_SUCCESS.

If there are in-progress calls to one or more of the client module's NPI callback functions when the provider module's *ProviderDetachClient* callback function is called, then the *ProviderDetachClient* callback function should return STATUS_PENDING. In this case, the provider module must call the **NmrProviderDetachClientComplete** function after all in-progress calls to the client module's NPI callback functions have completed. The call to **NmrProviderDetachClientComplete** notifies the NMR that detachment of the provider module from the client module is complete.

For more information about how to track the number of in-progress calls to a client module's NPI callback functions, see Programming Considerations.

If a provider module implements a *ProviderCleanupBindingContext* callback function, the NMR calls the provider module's *ProviderCleanupBindingContext* callback function after both the provider module and the client module have completed detachment from each other. A provider module's *ProviderCleanupBindingContext* callback function should perform any necessary cleanup of the data contained within the provider module's binding context structure. It should then free the memory for the binding context structure if the provider module dynamically allocated the memory for the structure.

For example:

C++

```
// ProviderDetachClient callback function
NTSTATUS
  ProviderDetachClient(
    IN PVOID ProviderBindingContext
    )
{
  PPROVIDER_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext = (PPROVIDER_BINDING_CONTEXT)ProviderBindingContext;

  // Set a flag indicating that the provider module is detaching
  // from the client module so that no more calls are made to
  // the client module's NPI callback functions.
  ...

  // Check if there are no in-progress NPI callback function calls
  // to the client module
  if (...)
  {
    // Return success status indicating detachment is complete
    return STATUS_SUCCESS;
  }

  // There are one or more in-progress NPI callback function
  // calls to the client module
  else
  {
    // Return pending status indicating detachment is pending
    // completion of the in-progress NPI callback function calls
    return STATUS_PENDING;

    // When the last in-progress call to the client module's
    // NPI callback functions completes, the provider module
    // must call NmrProviderDetachClientComplete() with the
    // binding handle for the attachment to the client module.
  }
}

// ProviderCleanupBindingContext callback function
VOID
  ProviderCleanupBindingContext(
    IN PVOID ProviderBindingContext
    )
{
  PPROVIDER_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext = (PPROVIDER_BINDING_CONTEXT)ProviderBindingContext;
  // Clean up the provider binding context structure
  ...

  // Free the memory for provider's binding context structure
  ExFreePoolWithTag(
    BindingContext,
    BINDING_CONTEXT_POOL_TAG
    );
}
```

Unloading a Provider Module

Article • 12/15/2021

To unload a provider module, the operating system calls the provider module's **Unload** function. See Initializing and Registering a Provider Module for more information about how to specify a provider module's **Unload** function during initialization.

A provider module's **Unload** function ensures that the provider module is deregistered from the Network Module Registrar (NMR) before the provider module is unloaded from system memory. A provider module initiates deregistration from the NMR by calling the **NmrDeregisterProvider** function, which it typically calls from its **Unload** function. A provider module must not return from its **Unload** function until after it has been completely deregistered from the NMR. If the call to **NmrDeregisterProvider** returns STATUS_PENDING, the provider module must call the **NmrWaitForProviderDeregisterComplete** function to wait for the deregistration to complete before it returns from its **Unload** function.

For example:

```C++
// Variable containing the handle for the registration
HANDLE ProviderHandle;

// Unload function
VOID
  Unload(
    IN PDRIVER_OBJECT DriverObject
    )
{
  NTSTATUS Status;

  // Deregister the provider module from the NMR
  Status =
    NmrDeregisterProvider(
      ProviderHandle
      );

  // Check if pending
  if (Status == STATUS_PENDING)
  {
    // Wait for the deregistration to be completed
    NmrWaitForProviderDeregisterComplete(
      ProviderHandle
      );
  }

  // An error occurred
```

```
    else
    {
      // Handle error
      ...
    }
  }
```

If a provider module is registered as a provider of multiple Network Programming Interfaces (NPIs), it must call **NmrDeregisterProvider** for each NPI that it supports. If a network module is registered as both a provider module and a client module (that is, it is a provider of one NPI and a client of another NPI), it must call both **NmrDeregisterProvider** and **NmrDeregisterClient**.

A network module must wait until all of the deregistrations are complete before returning from its **Unload** function.

A provider module is not required to call **NmrDeregisterProvider** from within its **Unload** function. For example, in the situation where a provider module is a subcomponent of a complex driver, the deregistration of the provider module might occur when the provider module subcomponent is deactivated. However, in such a situation the driver must still ensure that the provider module has been completely deregistered from the NMR before returning from its **Unload** function.

Programming Considerations

Article • 12/15/2021

A network module should use some form of reference counting to keep track of the number of in-progress calls to an attached network module's Network Programming Interface (NPI) functions. This will facilitate detaching from an attached network module when one of the two network modules deregisters with the NMR. A network module cannot complete detachment until there are no in-progress calls to the attached network module's NPI functions. A network module must also ensure that no more calls to the previously attached network module will be initiated once the network modules are detached.

For example, a client module might use an implementation similar to the following for tracking the number of in-progress calls to an attached provider module's NPI functions:

C++

```cpp
// Context structure for the client's binding to a provider module
typedef struct CLIENT_BINDING_CONTEXT_ {
  LIST_ENTRY Link;

    Status = STATUS_PENDING;
  }

  // Release the detach spin lock from DPC level
  KeReleaseInStackQueuedSpinLockFromDpcLevel(
    &DetachLockHandle
    );

  // Release the binding context list spin lock
  KeReleaseInStackQueuedSpinLock(
    &BindingContextListLockHandle
    );

  // Return the status of the detachment
  return Status;
}
```

Likewise, a provider module might use an implementation along the same lines as the above client module example for tracking the number of in-progress calls to an attached client module's NPI callback functions.

Note The above code example shows one possible method of tracking the number of in-progress calls to an attached network module's NPI functions. A network module might use an alternate method depending on the implementation details of the particular NPI that the network module supports.

Roadmap for Developing Network Drivers with Winsock Kernel

Article • 11/29/2022

To create a networking driver package that uses the kernel-mode socket programming features of Winsock Kernel (WSK), follow these steps:

- **Step 1:** Learn about Windows architecture and drivers.

  You must understand the fundamentals of how drivers work in Windows operating systems. Knowing the fundamentals will help you make appropriate design decisions and let you streamline your development process. For more information about driver fundamentals, see Concepts for all driver developers.

- **Step 2:** Learn about the Network Driver Interface Specification (NDIS).

  Your driver package will typically use Network Driver Interface Specification (NDIS) interfaces. For more information about NDIS and NDIS miniport drivers, see the following topics:

  Windows Network Architecture and the OSI Model

  NDIS Miniport Drivers

  Writing NDIS Miniport Drivers

  Network Driver Programming Considerations

- **Step 3:** Determine additional network components to use in your driver.

  In addition to the core NDIS features, you can use the following additional Windows network components with kernel-mode drivers, depending on the hardware configuration:

  IP Helper

  Windows Filtering Platform Callout Drivers

  Native 802.11 Wireless LAN

  Mobile Broadband Network Interface

- **Step 4:** Learn the fundamentals of Winsock Kernel.

Winsock Kernel is supported in Windows Vista and later versions of Windows. For information about how to use Winsock Kernel, see Introduction to Winsock Kernel.

A simpler, more generic network programming interface that you can use in network drivers is Network Module Registrar.

- **Step 5:** Determine additional Windows driver design decisions.

  For information about how to make additional Windows design decisions, see Creating Reliable Kernel-Mode Drivers, Programming Issues for 64-Bit Drivers, and Creating International INF Files.

- **Step 6:** Learn about the Windows driver build, test, and debug processes and tools.

  Building a driver differs from building a user-mode application. For information about Windows driver build, debug, and test processes, driver signing, and Windows Hardware Lab Kit (HLK) testing, see Building, Debugging, and Testing Drivers. For information about tools for building, testing, verifying, and debugging, see Driver Development Tools.

- **Step 7:** Review the Winsock Kernel (WSK TCP Echo Server) driver sample in the Windows driver samples repository on GitHub.

- **Step 8:** Develop, build, test, and debug your driver.

  For information about iterative building, testing, and debugging, see Overview of Build, Debug, and Test Process. This process helps ensure that you build a driver that works.

- **Step 9:** Create a driver package for your driver.

  For information about how to install drivers, see Providing a Driver Package.

- **Step 10:** Sign and distribute your driver.

  The final step is to sign (optional) and distribute the driver. If your driver meets the quality standards that are defined for the Windows Hardware Lab Kit (HLK), you can distribute it through the Microsoft Windows Update program. For more information about how to distribute a driver, see Get started with the hardware submission process.

These are the basic steps. Additional steps might be necessary based on the needs of your individual driver.

Introduction to Winsock Kernel

Article • 12/15/2021

Winsock Kernel (WSK) is a kernel-mode Network Programming Interface (NPI). With WSK, kernel-mode software modules can perform network I/O operations using the same socket programming concepts that are supported by user-mode Winsock2. The WSK NPI supports familiar socket operations such as socket creation, binding, connection establishment, and data transfers (send and receive). However, while the WSK NPI supports most of the same socket programming concepts as user-mode Winsock2, it is a completely new and different interface with unique characteristics such as asynchronous I/O that uses IRPs and event callbacks to enhance performance.

Kernel-mode network modules targeted for Windows Vista and later versions of Microsoft Windows should use WSK instead of TDI because WSK provides improved performance and easier programming. Filter drivers should implement the Windows Filtering Platform on Windows Vista, and TDI clients should implement WSK.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Winsock Kernel Overview Topics

Article • 12/15/2021

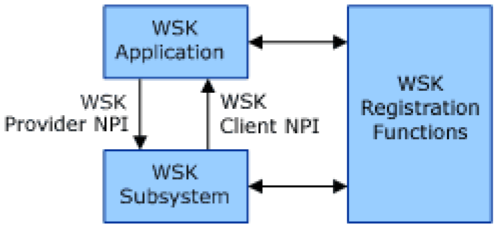
This section provides an overview of Winsock Kernel (WSK) and includes the following topics:

- Winsock Kernel Architecture
- Winsock Kernel Objects
- Winsock Kernel Socket Categories
- Winsock Kernel Events
- Using Winsock Kernel Functions vs. Event Callback Functions
- Winsock Kernel Dispatch Tables
- Winsock Kernel Extension Interfaces
- Using IRPs with Winsock Kernel Functions

Winsock Kernel Architecture

Article • 12/15/2021

The architecture of Winsock Kernel (WSK) is shown in the following diagram.



At the core of the WSK architecture is the WSK subsystem. The WSK subsystem is a network module that implements the provider side of the WSK Network Programming Interface (NPI). The WSK subsystem interfaces with transport providers on its lower edge that provide support for various transport protocols.

Attached to the WSK subsystem are WSK applications. WSK applications are kernel-mode software modules that implement the client side of the WSK NPI in order to perform network I/O operations. (In this context, "client" should not be confused with the term as used in client-server systems). . The WSK subsystem can call the functions in the WSK client NPI to notify the WSK application of asynchronous events.

WSK applications discover and attach to the WSK subsystem by using a set of WSK registration functions. Applications can use these functions to dynamically detect when the WSK subsystem is available and to exchange dispatch tables that constitute the provider and client side implementations of the WSK NPI.

Alternately, WSK applications can attach to the WSK subsystem by using the Network Module Registrar (NMR). For more information, see Using NMR for WSK Registration and Unregistration.

Winsock Kernel Objects

Article • 12/15/2021

The Winsock Kernel (WSK) Network Programming Interface (NPI) is designed around two main object types: *Client* and *Socket* .

Client Object

A *client object* represents the attachment, or binding, between a WSK application and the WSK subsystem. A client object is represented by the **WSK_CLIENT** structure. A pointer to a client object is returned to a WSK application during the process of attachment to the WSK subsystem. A WSK application passes this pointer to all WSK functions that operate at the client object level.

Socket Object

A *socket object* represents a network socket that can be used for network I/O. A socket object is represented by the **WSK_SOCKET** structure. A pointer to a socket object is returned to a WSK application when the application creates a new socket or when the application accepts an incoming connection. A WSK application passes this pointer to all WSK functions that are specific to a particular socket.

Winsock Kernel Socket Categories

Article • 12/15/2021

The Winsock Kernel (WSK) Network Programming Interface (NPI) defines five different categories of sockets: *basic sockets*, *listening sockets*, *datagram sockets*, *connection-oriented sockets*, and *stream sockets*. Each WSK socket category has unique functionality and supports a different set of socket functions. A WSK application must specify which category of WSK socket it is creating whenever it creates a new socket. The purpose for each WSK socket category is as follows:

Basic Sockets
Basic sockets are used only to get and set transport stack socket options or to perform socket I/O control operations. Basic sockets cannot be bound to a local transport address and do not support sending or receiving network data.

Listening Sockets
Listening sockets are used to listen for incoming connections from remote transport addresses. The functionality of a listening socket includes all of the functionality of a basic socket.

Datagram Sockets
Datagram sockets are used to send and receive datagrams. The functionality of a datagram socket includes all of the functionality of a basic socket.

Connection-Oriented Sockets
Connection-oriented sockets are used to send and receive network data over established connections. The functionality of a connection-oriented socket includes all of the functionality of a basic socket.

Stream Sockets
Stream sockets are used to either listen for incoming connections from remote transport addresses (act as a listening socket), or to send and receive network data over established connections (act as a connection-oriented socket). Use a stream socket when you do not know at the time of socket creation if you want a listening socket or a connection-oriented socket. The functionality of a stream socket includes all of the functionality of a basic socket.

Winsock Kernel Events

Article • 12/15/2021

The Winsock Kernel (WSK) subsystem can asynchronously notify a WSK application when certain socket events occur, such as when new data has been received on a socket or when a socket has been disconnected. In order for a WSK application to be asynchronously notified of socket events, the WSK application must implement the appropriate event callback functions and enable those event callback functions on the sockets that it creates.

Note A WSK application is not required to implement or use event callback functions. A WSK application can perform most WSK socket operations by calling the appropriate WSK socket functions. The only WSK feature that requires using event callback functions is conditional-accept mode on listening sockets. For more information about the advantages and disadvantages between using WSK functions versus using event callback functions, see Using Winsock Kernel Functions vs. Event Callback Functions.

Each WSK socket category supports a different set of socket events.

Basic sockets

Basic sockets do not support any socket events.

Listening sockets

Event	Event callback function
An incoming connection has been accepted.	*WskAcceptEvent*
An incoming connection request has arrived.	*WskInspectEvent*
An incoming connection request has been dropped.	*WskAbortEvent*

* Applies only to listening sockets that have conditional-accept mode enabled. For more information about using conditional accept mode with listening sockets, see Listening for and Accepting Incoming Connections.

Datagram sockets

Event	Event callback function
One or more new datagrams have been received.	*WskReceiveFromEvent*

Connection-oriented sockets

Event	Event callback function
New data has been received.	*WskReceiveEvent*
The socket has been disconnected.	*WskDisconnectEvent*
The ideal send backlog size has changed.	*WskSendBacklogEvent*

When a WSK application creates a socket, the socket's event callback functions are disabled by default. A WSK application must enable a socket's event callback functions in order for the WSK subsystem to call the socket's event callback functions when socket events occur. For more information about enabling and disabling a socket's event callback functions, see Enabling and Disabling Event Callback Functions.

If a WSK application registers an extension interface for a socket, the extension interface might support additional events. For more information about registering an extension interface for a socket, see Registering an Extension Interface.

The WSK subsystem can also notify a WSK application of events that are not specific to a particular socket. In order for a WSK application to be notified of these events, the WSK application must implement a *WskClientEvent* event callback function. There are currently no events defined that are not specific to a particular socket. A WSK application's *WskClientEvent* event callback function is always enabled and cannot be disabled.

A WSK application's event callback functions must not wait for completion of other WSK requests in the context of WSK completion or event callback functions. The callback may initiate other WSK requests assuming that it doesn't spend too much time at DISPATCH_LEVEL or exhaust the kernel stack, but it must not wait for their completion even when the callback is called at IRQL = PASSIVE_LEVEL.

Using Winsock Kernel Functions vs. Event Callback Functions

Article • 12/15/2021

For certain socket operations, a Winsock Kernel (WSK) application can either call one of the socket's WSK functions to perform the operation or implement and enable an event callback function on the socket that the WSK subsystem calls when the event associated with the operation occurs. For example, when receiving data on a connection-oriented socket, a WSK application can either make calls to the socket's **WskReceive** function, or implement and enable a *WskReceiveEvent* event callback function on the socket. The requirements of a WSK application dictate which method the application should use. Examples for how to use both methods are provided throughout the WSK documentation.

The following lists summarize some key points for each method.

Using Winsock Kernel Functions

- The WSK application drives the socket operations, meaning the WSK application controls when the socket operations occur. This might simplify the synchronization required by the WSK application.

- The WSK application provides IRPs to the socket functions. These IRPs are queued by the WSK subsystem until the socket operation completes. For more information about using IRPs with WSK functions, see Using IRPs with Winsock Kernel Functions.

- The WSK application can perform blocking socket operations by waiting for the IRP for each operation to be completed by the WSK subsystem.

- The WSK application might need to keep multiple socket operations queued in some situations in order to ensure high performance data transfer on connection-oriented sockets, to prevent incoming datagrams from being dropped on datagram sockets, or to prevent incoming connections being dropped on listening sockets.

- The WSK application provides the data buffers for the data transfer operations. This reduces the number of times the data might need to be copied. However, if a WSK application keeps multiple data transfer operations queued, the application must provide data buffers to the WSK subsystem for each queued data transfer operation. Thus, the WSK application might require additional memory resources.

Using Event Callback Functions

- The WSK subsystem drives the socket operations, meaning the WSK subsystem notifies the WSK application of the socket's events by calling the socket's event callback functions. The WSK application might require more complex synchronization to handle the asynchronous nature of the event callback functions.

- The WSK application does not use IRPs for the socket operations.

- The WSK application does not need to queue socket operations. The WSK subsystem calls the WSK application's event callback functions as soon as the socket's events occur. If the WSK application can keep up with the rate that a socket's event callback functions are called, using event callback functions could provide the highest performance and least chance of dropping datagrams or incoming connections.

- The WSK subsystem supplies the data buffers for data transfer operations. The WSK application must release these data buffers back to the WSK subsystem either immediately, or within a reasonable amount of time, so that the WSK subsystem does not run out of memory resources. Thus, the WSK application might need to copy the data from the data buffers that are owned by the WSK subsystem into its own data buffers.

Note The above lists are not necessarily exhaustive. There might be other points to consider when choosing which method is the best choice for a particular WSK application.

Winsock Kernel Dispatch Tables

Article • 12/15/2021

The socket object for a Winsock Kernel (WSK) socket contains a pointer to a provider dispatch table structure that contains function pointers to the socket functions supported by the socket. A WSK application calls the functions in the provider dispatch table structure to perform network I/O operations on the socket. Because each WSK socket category supports a different set of socket functions, the WSK Network Programming Interface (NPI) defines a different provider dispatch table structure for each category of WSK socket.

Socket category	Dispatch table structure
Basic socket	WSK_PROVIDER_BASIC_DISPATCH
Listening socket	WSK_PROVIDER_LISTEN_DISPATCH
Datagram socket	WSK_PROVIDER_DATAGRAM_DISPATCH
Connection-oriented socket	WSK_PROVIDER_CONNECTION_DISPATCH

If a WSK application uses event callback functions for the sockets that it creates, it must provide a client dispatch table structure that contains function pointers to the socket's event callback functions whenever it creates a new socket. Because each WSK socket category supports a different set of event callback functions, the WSK NPI defines a different client dispatch table structure for each category of WSK socket.

Socket category	Dispatch table structure
Listening socket	WSK_CLIENT_LISTEN_DISPATCH
Datagram socket	WSK_CLIENT_DATAGRAM_DISPATCH
Connection-oriented socket	WSK_CLIENT_CONNECTION_DISPATCH

Note Basic sockets do not support any event callback functions. Therefore, no client dispatch table structure is defined for basic sockets.

Winsock Kernel Extension Interfaces

Article • 12/15/2021

The Winsock Kernel (WSK) Network Programming Interface (NPI) includes support for *extension interfaces*. The WSK subsystem can use extension interfaces to extend the functionality of WSK sockets beyond the set of socket functions and event callback functions currently defined by the WSK NPI. Each extension interface is defined by an NPI that is independent of the WSK NPI. Currently no extension interfaces have been defined.

A WSK application can register for an extension interface that is supported by the WSK subsystem by using the **SIO_WSK_REGISTER_EXTENSION** socket IOCTL operation. A WSK application registers for extension interfaces on a socket-by-socket basis.

For more information about registering an extension interface, see Registering an Extension Interface.

Using IRPs with Winsock Kernel Functions

Article • 12/15/2021

The Winsock Kernel (WSK) Network Programming Interface (NPI) uses IRPs for asynchronous completion of network I/O operations. Each WSK function takes a pointer to an IRP as a parameter. The WSK subsystem completes the IRP after the operation performed by the WSK function is complete.

An IRP that a WSK application uses to pass to a WSK function can originate in one of the following ways.

- The WSK application allocates the IRP by calling the **IoAllocateIrp** function. In this situation, the WSK application must allocate the IRP with at least one I/O stack location.

- The WSK application reuses a completed IRP that it previously allocated. In this situation, the WSK must call the **IoReuseIrp** function to reinitialize the IRP.

- The WSK application uses an IRP that was passed down to it either by a higher level driver or by the I/O manager. In this situation, the IRP must have at least one remaining I/O stack location available for use by the WSK subsystem.

After a WSK application has an IRP to use for calling a WSK function, it can set an **IoCompletion** routine for the IRP to be called when the IRP is completed by the WSK subsystem. A WSK application sets an **IoCompletion** routine for an IRP by calling the **IoSetCompletionRoutine** function. Depending upon how the IRP originated, an **IoCompletion** routine is either required or optional.

- If the WSK application allocated the IRP, or is reusing an IRP that it previously allocated, then it must set an **IoCompletion** routine for the IRP before calling a WSK function. In this situation, the WSK application must specify **TRUE** for the *InvokeOnSuccess*, *InvokeOnError*, and *InvokeOnCancel* parameters that are passed to the **IoSetCompletionRoutine** function to ensure that the **IoCompletion** routine is always called. Furthermore, the **IoCompletion** routine that is set for the IRP must always return STATUS_MORE_PROCESSING_REQUIRED to terminate the completion processing of the IRP. If the WSK application is done using the IRP after the **IoCompletion** routine has been called, then it should call the **IoFreeIrp** function to free the IRP before returning from the **IoCompletion** routine. If the WSK application does not free the IRP then it can reuse the IRP for a call to another WSK function.

- If the WSK application uses an IRP that was passed down to it by a higher level driver or by the I/O manager, it should set an **IoCompletion** routine for the IRP before calling the WSK function only if it must be notified when the operation performed by the WSK function has completed. If the WSK application does not set an **IoCompletion** routine for the IRP, then when the IRP is completed the IRP will be passed back up to the higher level driver or to the I/O manager as per normal IRP completion processing. If the WSK application sets an **IoCompletion** routine for the IRP, the **IoCompletion** routine can either return STATUS_SUCCESS or STATUS_MORE_PROCESSING_REQUIRED. If the **IoCompletion** routine returns STATUS_SUCCESS, the IRP completion processing will continue normally. If the **IoCompletion** routine returns STATUS_MORE_PROCESSING_REQUIRED, the WSK application must complete the IRP by calling **IoCompleteRequest** after it has finished processing the results of the operation that was performed by the WSK function. A WSK application should never free an IRP that was passed down to it by a higher level driver or by the I/O manager.

Note If the WSK application sets an **IoCompletion** routine for an IRP that was passed down to it by a higher level driver or by the I/O manager, then the **IoCompletion** routine must check the **PendingReturned** member of the IRP and call the **IoMarkIrpPending** function if the **PendingReturned** member is **TRUE**. For more information, see Implementing an IoCompletion Routine.

Note A WSK application should not call new WSK functions in the context of the **IoCompletion** routine. Doing so may result in recursive calls and exhaust the kernel mode stack. When executing at IRQL = DISPATCH_LEVEL, this can also lead to starvation of other threads.

A WSK application does not initialize the IRPs that it passes to the WSK functions other than setting an **IoCompletion** routine. When a WSK application passes an IRP to a WSK function, the WSK subsystem sets up the next I/O stack location on behalf of the application.

The following code example shows how a WSK application can allocate and use an IRP when performing a receive operation on a socket.

C++

```
// Prototype for the receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );
```

```
// Function to receive data
NTSTATUS
  ReceiveData(
    PWSK_SOCKET Socket,
    PWSK_BUF DataBuffer
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ReceiveComplete,
    DataBuffer,  // Use the data buffer for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the receive operation on the socket
  Status =
    Dispatch->WskReceive(
      Socket,
      DataBuffer,
      0,  // No flags are specified
      Irp
      );

  // Return the status of the call to WskReceive()
  return Status;
}

// Receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DataBuffer;
  ULONG ByteCount;

  // Check the result of the receive operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the data buffer
    DataBuffer = (PWSK_BUF)Context;

    // Get the number of bytes received
    ByteCount = (ULONG)(Irp->IoStatus.Information);

    // Process the received data
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

The model shown in the previous example, where the WSK application allocates an IRP and then frees it in the completion routine, is the model that is used in the examples throughout the remainder of the WSK documentation.

The following code example shows how a WSK application can use an IRP that has been passed to it by a higher level driver or by the I/O manager when performing a receive operation on a socket.

C++

```
// Prototype for the receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to receive data
NTSTATUS
  ReceiveData(
    PWSK_SOCKET Socket,
    PWSK_BUF DataBuffer,
    PIRP Irp;  // IRP from a higher level driver or the I/O manager
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Set the completion routine for the IRP such that it is
  // only called if the receive operation succeeds.
  IoSetCompletionRoutine(
    Irp,
    ReceiveComplete,
    DataBuffer,  // Use the data buffer for the context
    TRUE,
    FALSE,
    FALSE
    );

  // Initiate the receive operation on the socket
  Status =
    Dispatch->WskReceive(
      Socket,
      DataBuffer,
      0,  // No flags are specified
      Irp
      );

  // Return the status of the call to WskReceive()
  return Status;
}

// Receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DataBuffer;
  ULONG ByteCount;
  // Since the completion routine was only specified to
  // be called if the operation succeeds, this should
  // always be true.
  ASSERT(Irp->IoStatus.Status == STATUS_SUCCESS);

  // Check the pending status of the IRP
  if (Irp->PendingReturned == TRUE)
  {
    // Mark the IRP as pending
    IoMarkIrpPending(Irp);
  }

  // Get the pointer to the data buffer
  DataBuffer = (PWSK_BUF)Context;

  // Get the number of bytes received
  ByteCount = (ULONG)(Irp->IoStatus.Information);

  // Process the received data
  ...

  // Return STATUS_SUCCESS to continue the
  // completion processing of the IRP.
  return STATUS_SUCCESS;
}
```

For more information about using IRPs, see Handling IRPs.

Winsock Kernel Operations Topics

Article • 12/15/2021

This section discusses Winsock Kernel (WSK) operations and includes the following topics:

- Registering a Winsock Kernel Application
- Performing Control Operations on a Client Object
- Creating Sockets
- Performing Control Operations on a Socket
- Enabling and Disabling Event Callback Functions
- Binding a Socket to a Transport Address
- Listening for and Accepting Incoming Connections
- Establishing a Connection with a Destination
- Sending and Receiving Data
- Disconnecting a Socket from a Destination
- Closing a Socket
- Registering an Extension Interface
- Unregistering a Winsock Kernel Application
- Resolving Host Names and IP Addresses
- WSK Client Control Operations
- WSK Socket IOCTL Operations
- WSK Socket Options
- WSK data types

Registering a Winsock Kernel Application

Article • 12/15/2021

WSK Client Object Registration

A Winsock Kernel (WSK) application must register as a WSK client by calling the **WskRegister** function. **WskRegister** requires the WSK application to initialize and pass a pointer to its WSK client's Network Programming Interface (NPI)(a **WSK_CLIENT_NPI** structure) and a WSK registration object (a **WSK_REGISTRATION** structure) that will be initialized by **WskRegister** upon successful return.

The following code example shows how a WSK application can register as a WSK client.

C++

```cpp
// Include the WSK header file
#include "wsk.h"

// WSK Client Dispatch table that denotes the WSK version
// that the WSK application wants to use and optionally a pointer
// to the WskClientEvent callback function
const WSK_CLIENT_DISPATCH WskAppDispatch = {
  MAKE_WSK_VERSION(1,0), // Use WSK version 1.0
  0,    // Reserved
  NULL  // WskClientEvent callback not required for WSK version 1.0
};

// WSK Registration object
WSK_REGISTRATION WskRegistration;

// DriverEntry function
NTSTATUS
  DriverEntry(
    PDRIVER_OBJECT DriverObject,
    PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS Status;
  WSK_CLIENT_NPI wskClientNpi;

  .
  .
  .

  // Register the WSK application
  wskClientNpi.ClientContext = NULL;
  wskClientNpi.Dispatch = &WskAppDispatch;
  Status = WskRegister(&wskClientNpi, &WskRegistration);

  if(!NT_SUCCESS(Status)) {
      .
      .
      .
      return Status;
  }

  .
  .
  .
}
```

A WSK application is not required to call **WskRegister** from within its **DriverEntry** function. For example, if a WSK application is a subcomponent of a complex driver, the registration of the application might occur only when the WSK application subcomponent is activated.

A WSK application must keep the **WSK_CLIENT_DISPATCH** structure passed to **WskRegister** valid and resident in memory until **WskDeregister** is called and the registration is no longer valid. The **WSK_REGISTRATION** structure must also be kept valid and resident in memory until the WSK application stops making calls to the other WSK registration functions. The previous code example keeps these two structures in the global data section of the driver, thereby keeping the structure data resident in memory until the driver is unloaded.

WSK Provider NPI Capture

After a WSK application has registered as a WSK client with **WskRegister**, it must use the **WskCaptureProviderNPI** function to capture the WSK provider NPI from the WSK subsystem in order to start using the WSK interface.

Because the WSK subsystem might not yet be ready when a WSK application attempts to capture the WSK provider NPI, the **WskCaptureProviderNPI** function allows the WSK application to poll or wait for the WSK subsystem to become ready as follows:

- If the *WaitTimeout* parameter is WSK_NO_WAIT, the function will always return immediately without waiting.
- If *WaitTimeout* is WSK_INFINITE_WAIT, the function will wait until the WSK subsystem becomes ready.
- If *WaitTimeout* is any other value, the function will return either when the WSK subsystem becomes ready or when the wait time, in milliseconds, reaches the value

of *WaitTimeout*, whichever occurs first.

Important To avoid adversely affecting the start of other drivers and services, a WSK application that calls **WskCaptureProviderNPI** from its **DriverEntry** function should not set the *WaitTimeout* parameter to WSK_INFINITE_WAIT or an excessive wait time. Also, if a WSK application starts very early in the system startup phase, it should wait for the WSK subsystem to become ready in a different worker thread than the one in which **DriverEntry** runs.

If the call to **WskCaptureProviderNPI** fails with STATUS_NOINTERFACE, the WSK application can use the WskQueryProviderCharacteristics function to discover the range of WSK NPI versions supported by the WSK subsystem. The WSK application can call **WskDeregister** to unregister its current registration instance, and then register again by using a different WSK_CLIENT_DISPATCH instance that uses a supported WSK NPI version.

When **WskCaptureProviderNPI** returns successfully, its *WskProviderNpi* parameter points to a WSK provider NPI (WSK_PROVIDER_NPI) ready for use by the WSK application. The WSK_PROVIDER_NPI structure contains pointers to the WSK client object (WSK_CLIENT) and the WSK_PROVIDER_DISPATCH dispatch table of WSK functions that the WSK application can use to create WSK sockets and perform other operations on the WSK client object. After the WSK application is finished using the WSK_PROVIDER_DISPATCH functions, it must release the WSK provider NPI by calling WskReleaseProviderNPI.

The following code example shows how a WSK application can capture the WSK provider NPI, use it to create a socket, and then release it.

C++

```
// WSK application routine that waits for WSK subsystem
// to become ready and captures the WSK Provider NPI
NTSTATUS
  WskAppWorkerRoutine(
    )
{
  NTSTATUS Status;
  WSK_PROVIDER_NPI wskProviderNpi;

  // Capture the WSK Provider NPI. If WSK subsystem is not ready yet,
  // wait until it becomes ready.
  Status = WskCaptureProviderNPI(
    &WskRegistration, // must have been initialized with WskRegister
    WSK_INFINITE_WAIT,
    &wskProviderNpi
    );
  if(!NT_SUCCESS(Status))
  {
    // The WSK Provider NPI could not be captured.
    if( Status == STATUS_NOINTERFACE ) {
      // WSK application's requested version is not supported
    }
    else if( status == STATUS_DEVICE_NOT_READY ) {
      // WskDeregister was invoked in another thread thereby causing
      // WskCaptureProviderNPI to be canceled.
    }
    else {
      // Some other unexpected failure has occurred
    }

    return Status;
  }

  // The WSK Provider NPI has been captured.
  // Create and set up a listening socket that accepts
   // incoming connections.
  Status = CreateListeningSocket(&wskProviderNpi, ...);

  // The WSK Provider NPI will not be used any more.
  // So, release it here immediately.
  WskReleaseProviderNPI(&WskRegistration);

  // Return result of socket creation routine
  return Status;

}
```

A WSK application can call WskCaptureProviderNPI more than once. For each call to **WskCaptureProviderNPI** that returns successfully, there must be a corresponding call to WskReleaseProviderNPI. A WSK application must not make any further calls to the functions in WSK_PROVIDER_DISPATCH after calling **WskReleaseProviderNPI**.

Performing Control Operations on a Client Object

Article • 12/15/2021

After a Winsock Kernel (WSK) application has successfully attached to the WSK subsystem, it can perform control operations on the client object (**WSK_CLIENT**) that was returned by the WSK subsystem during attachment. These control operations are not specific to a particular socket, but instead have a more general scope. For more information about each of the control operations that can be performed on a client object, see WSK Client Control Operations.

A WSK application performs client control operations by calling the **WskControlClient** function. The **WskControlClient** function is pointed to by the **WskControlClient** member of the **WSK_PROVIDER_DISPATCH** structure that was returned by the WSK subsystem during attachment.

The following code example shows how a WSK application can use the **WSK_TRANSPORT_LIST_QUERY** client control operation to retrieve a list of available network transports that can be specified when creating a new socket.

```C++
// Function to retrieve a list of available network transports
NTSTATUS
  GetTransportList(
    PWSK_PROVIDER_NPI WskProviderNpi,
    PWSK_TRANSPORT TransportList,
    ULONG MaxTransports,
    PULONG TransportsRetrieved
    )
{
  SIZE_T BytesRetrieved;
  NTSTATUS Status;

  // Perform client control operation
  Status =
    WskProviderNpi->Dispatch->
        WskControlClient(
          WskProviderNpi->Client,
          WSK_TRANSPORT_LIST_QUERY,
          0,
          NULL,
          MaxTransports * sizeof(WSK_TRANSPORT),
          TransportList,
          &BytesRetrieved,
          NULL  // No IRP for this control operation
          );

  // Convert bytes retrieved to transports retrieved
  TransportsRetrieved = BytesRetrieved / sizeof(WSK_TRANSPORT);

  // Return status of client control operation
  return Status;
}
```

Creating Sockets

Article • 12/15/2021

After a Winsock Kernel (WSK) application has successfully attached to the WSK subsystem, it can create sockets that can be used for network I/O operations. A WSK application creates sockets by calling the **WskSocket** function. The **WskSocket** function is pointed to by the **WskSocket** member of the **WSK_PROVIDER_DISPATCH** structure that was returned by the WSK subsystem during attachment.

A WSK application must specify which category of WSK socket it is creating whenever it creates a new socket. For more information about WSK socket categories, see Winsock Kernel Socket Categories.

A WSK application must also specify the address family, socket type, and protocol whenever it creates a new socket. For more information about the address families supported by WSK, see WSK Address Families.

When creating a new socket, a WSK application must provide a socket context value and a pointer to a client dispatch table structure if the application will be enabling any event callback functions on the socket. For more information about enabling event callback functions on a socket, see Enabling and Disabling Event Callback Functions.

If the socket is created successfully, the **IoStatus.Information** field of the IRP contains a pointer to a socket object structure (**WSK_SOCKET**) for the new socket. For more information about using IRPs with WSK functions, see Using IRPs with Winsock Kernel Functions.

The following code example shows how a WSK application can create a listening socket.

C++

```
// Context structure for each socket
typedef struct _WSK_APP_SOCKET_CONTEXT {
  PWSK_SOCKET Socket;
  .
  .  // Other application-specific members
  .
} WSK_APP_SOCKET_CONTEXT, *PWSK_APP_SOCKET_CONTEXT;

// Prototype for the socket creation IoCompletion routine
NTSTATUS
  CreateListeningSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );
```

```
// Function to create a new listening socket
NTSTATUS
  CreateListeningSocket(
    PWSK_PROVIDER_NPI WskProviderNpi,
    PWSK_APP_SOCKET_CONTEXT SocketContext,
    PWSK_CLIENT_LISTEN_DISPATCH Dispatch,
    )
{
  PIRP Irp;
  NTSTATUS Status;

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    CreateListeningSocketComplete,
    SocketContext,
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the creation of the socket
  Status =
    WskProviderNpi->Dispatch->
        WskSocket(
          WskProviderNpi->Client,
          AF_INET,
          SOCK_STREAM,
          IPPROTO_TCP,
          WSK_FLAG_LISTEN_SOCKET,
          SocketContext,
          Dispatch,
          NULL,
          NULL,
          NULL,
          Irp
          );

  // Return the status of the call to WskSocket()
  return Status;
}

// Socket creation IoCompletion routine
NTSTATUS
  CreateListeningSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_APP_SOCKET_CONTEXT SocketContext;

  // Check the result of the socket creation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the socket context
    SocketContext =
      (PWSK_APP_SOCKET_CONTEXT)Context;

    // Save the socket object for the new socket
    SocketContext->Socket =
      (PWSK_SOCKET)(Irp->IoStatus.Information);

    // Set any socket options for the new socket
    ...

    // Enable any event callback functions on the new socket
    ...

    // Perform any other initializations
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

For connection-oriented sockets, a WSK application can call the WskSocketConnect function to create, bind, and connect a socket in a single function call.

Performing Control Operations on a Socket

Article • 12/15/2021

After a Winsock Kernel (WSK) application has successfully created a socket, it can perform control operations on the socket. The control operations that can be performed on a socket include setting and retrieving socket options and executing socket IOCTL operations.

A WSK application performs control operations on a socket by calling the WskControlSocket function. The **WskControlSocket** function is pointed to by the **WskControlSocket** member of the socket's provider dispatch structure. A socket's provider dispatch structure is pointed to by the **Dispatch** member of the socket object structure (WSK_SOCKET) that was returned by the WSK subsystem during the creation of the socket.

The following code example shows how a WSK application can set the SO_EXCLUSIVEADDRUSE socket option on a datagram socket.

```C++
// Prototype for the control socket IoCompletion routine
NTSTATUS
  ControlSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to set the SO_EXCLUSIVEADDRUSE socket option
// on a datagram socket
NTSTATUS
  SetExclusiveAddrUse(
    PWSK_SOCKET Socket
    )
{
  PWSK_PROVIDER_DATAGRAM_DISPATCH Dispatch;
  PIRP Irp;
  ULONG SocketOptionState;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_DATAGRAM_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ControlSocketComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Set the socket option state to 1 to set the socket option
  SocketOptionState = 1;

  // Initiate the control operation on the socket
  Status =
    Dispatch->WskControlSocket(
      Socket,
      WskSetOption,
      SO_EXCLUSIVEADDRUSE,
      SOL_SOCKET,
      sizeof(ULONG),
      &SocketOptionState,
      0,
      NULL,
      NULL,
      Irp
      );

  // Return the status of the call to WskControlSocket()
  return Status;
}

// Control socket IoCompletion routine
NTSTATUS
  ControlSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;
  // Check the result of the control operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

For more information about each of the supported socket options, see WSK Socket Options.

The following code example shows how a WSK application can execute the SIO_WSK_SET_REMOTE_ADDRESS socket IOCTL operation on a datagram socket.

C++

```
// Prototype for the control socket IoCompletion routine
NTSTATUS
  ControlSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to perform the SIO_WSK_SET_REMOTE_ADDRESS socket
// IOCTL operation on a datagram socket
NTSTATUS
  SetRemoteAddress(
    PWSK_SOCKET Socket,
    PSOCKADDR RemoteAddress
    )
{
  PWSK_PROVIDER_DATAGRAM_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_DATAGRAM_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ControlSocketComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the IOCTL operation on the socket
  Status =
    Dispatch->WskControlSocket(
      Socket,
      WskIoctl,
 SIO_WSK_SET_REMOTE_ADDRESS,
      0,
      sizeof(SOCKADDR_IN),  // AF_INET
      RemoteAddress,
      0,
      NULL,
      NULL,
      Irp
      );

  // Return the status of the call to WskControlSocket()
  return Status;
}

// Control socket IoCompletion routine
NTSTATUS
  ControlSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;

  // Check the result of the control operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

For more information about each of the supported socket IOCTL operations, see WSK Socket IOCTL Operations.

Enabling and Disabling Event Callback Functions

Article • 12/15/2021

A Winsock Kernel (WSK) application can implement event callback functions that the WSK subsystem calls asynchronously to notify the application when certain events occur on a socket. A WSK application can provide a client dispatch table structure to the WSK subsystem whenever it creates a socket or accepts a socket on a listening socket. This dispatch table contains pointers to the WSK application's event callback functions for the new socket. If a WSK application does not implement any event callback functions for a particular socket, then it does not need to provide a client dispatch table structure to the WSK subsystem for that socket.

All of a socket's event callback functions, except for a listening socket's *WskInspectEvent* and *WskAbortEvent* event callback functions, can be enabled or disabled by using the **SO_WSK_EVENT_CALLBACK** socket option. A WSK application can enable multiple event callback functions on a socket at the same time. However, a WSK application must disable each event callback function individually.

The following code example shows how a WSK application can use the SO_WSK_EVENT_CALLBACK socket option to enable the *WskDisconnectEvent* and *WskReceiveEvent* event callback functions on a connection-oriented socket.

```C++
// Function to enable the WskDisconnectEvent and WskReceiveEvent
// event callback functions on a connection-oriented socket
NTSTATUS
  EnableDisconnectAndRecieveCallbacks(
    PWSK_SOCKET Socket
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  WSK_EVENT_CALLBACK_CONTROL EventCallbackControl;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Specify the WSK NPI identifier
  EventCallbackControl.NpiId = &NPI_WSK_INTERFACE_ID;

  // Set the event flags for the event callback functions that
  // are to be enabled on the socket
  EventCallbackControl.EventMask =
    WSK_EVENT_DISCONNECT | WSK_EVENT_RECEIVE;

  // Initiate the control operation on the socket
  Status =
    Dispatch->WskControlSocket(
      Socket,
      WskSetOption,
      SO_WSK_EVENT_CALLBACK,
      SOL_SOCKET,
      sizeof(WSK_EVENT_CALLBACK_CONTROL),
      &EventCallbackControl,
      0,
      NULL,
      NULL,
      NULL  // No IRP for this control operation
      );

  // Return the status of the call to WskControlSocket()
  return Status;
}
```

The following code example shows how a WSK application can use the **SO_WSK_EVENT_CALLBACK** socket option to disable the *WskReceiveEvent* event callback functions on a connection-oriented socket.

C++

```
// Prototype for the disable disconnect IoCompletion routine
NTSTATUS
  DisableDisconnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to disable the WskDisconnectEvent event
// callback functions on a connection-oriented socket
NTSTATUS
  DisableDisconnectCallback(
    PWSK_SOCKET Socket
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  WSK_EVENT_CALLBACK_CONTROL EventCallbackControl;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);
  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
 DisableDisconnectComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Specify the WSK NPI identifier
  EventCallbackControl.NpiId = &NPI_WSK_INTERFACE_ID;

  // Set the event flag for the event callback function that
  // is to be disabled on the socket along with the disable flag
  EventCallbackControl.EventMask =
    WSK_EVENT_DISCONNECT | WSK_EVENT_DISABLE;

  // Initiate the control operation on the socket
  Status =
    Dispatch->WskControlSocket(
      Socket,
      WskSetOption,
      SO_WSK_EVENT_CALLBACK,
      SOL_SOCKET,
      sizeof(WSK_EVENT_CALLBACK_CONTROL),
      &EventCallbackControl,
      0,
      NULL,
      NULL,
      Irp
      );

  // Return the status of the call to WskControlSocket()
  return Status;
}

// Disable disconnect IoCompletion routine
NTSTATUS
  DisableDisconnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;

  // Check the result of the control operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // The WskDisconnectEvent event callback
    // function is now disabled

    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

For listening sockets, the *WskInspectEvent* and *WskAbortEvent* event callback functions are enabled only if the WSK application enables conditional accept mode on the socket. A WSK application enables conditional accept mode on a listening socket by setting the **SO_CONDITIONAL_ACCEPT** socket option for the socket prior to binding the socket to a local transport address. For more information about how to set socket options, see Performing Control Operations on a Socket.

After conditional accept mode has been enabled on a listening socket, the socket's *WskInspectEvent* and *WskAbortEvent* event callback functions cannot be disabled. For more information about conditionally accepting incoming connections on listening sockets, see Listening for and Accepting Incoming Connections.

A listening socket can automatically enable event callback functions on connection-oriented sockets that are accepted by the listening socket's *WskAcceptEvent* event callback function. A WSK application automatically enables these callback functions by enabling the connection-oriented socket event callback functions on the listening socket. For more information about this process, see SO_WSK_EVENT_CALLBACK.

If a WSK application always enables certain event callback functions on every socket that it creates, the application can configure the WSK subsystem to automatically enable those event callback functions by using the WSK_SET_STATIC_EVENT_CALLBACKS client control operation. The event callback functions that are enabled in this manner are always enabled and cannot be disabled or re-enabled later by the WSK application. If a WSK application always enables certain event callback functions on every socket that it creates, the application should use this method to automatically enable those event callback functions because it will yield much better performance.

The following code example shows how a WSK application can use the WSK_SET_STATIC_EVENT_CALLBACKS client control operation to automatically enable the *WskReceiveFromEvent* event callback function on datagram sockets and the *WskReceiveEvent* event callback function on connection-oriented sockets.

C++

```
// Function to set static event callbacks
NTSTATUS
  SetStaticEventCallbacks(
    PWSK_APP_BINDING_CONTEXT BindingContext,
    )
{
  WSK_EVENT_CALLBACK_CONTROL EventCallbackControl;
  NTSTATUS Status;

  // Specify the WSK NPI identifier
  EventCallbackControl.NpiId = &NPI_WSK_INTERFACE_ID;

  // Set the event flags for the event callback functions that
  // are to be automatically enabled on every new socket
  EventCallbackControl.EventMask =
    WSK_EVENT_RECEIVE_FROM | WSK_EVENT_RECEIVE;

  // Perform client control operation
  Status =
    BindingContext->
      WskProviderDispatch->
        WskControlClient(
          BindingContext->WskClient,
          WSK_SET_STATIC_EVENT_CALLBACKS,
          sizeof(WSK_EVENT_CALLBACK_CONTROL),
          &EventCallbackControl,
          0,
          NULL,
          NULL,
          NULL  // No IRP for this control operation
          );

  // Return status of client control operation
  return Status;
}
```

If a WSK application uses the WSK_SET_STATIC_EVENT_CALLBACKS client control operation to automatically enable certain event callback functions, it must do so before it creates any sockets.

Binding a Socket to a Transport Address

Article • 12/15/2021

After a Winsock Kernel (WSK) application has successfully created a socket, it can bind that socket to a local transport address. A listening socket must be bound to a local transport address before it can accept incoming connections. A datagram socket must be bound to a local transport address before it can send or receive datagrams. A connection-oriented socket must be bound to a local transport address before it can connect to a remote transport address.

Note Basic sockets do not support sending or receiving network data. Therefore, a WSK application cannot bind a basic socket to a local transport address.

A WSK application binds a socket to a local transport address by calling the WskBind function. The **WskBind** function is pointed to by the **WskBind** member of the socket's provider dispatch structure. A socket's provider dispatch structure is pointed to by the **Dispatch** member of the socket object structure (WSK_SOCKET) that was returned by the WSK subsystem during the creation of the socket.

A socket can be bound to a local wildcard address. For more information about the behavior of a socket that has been bound to a local wildcard address, see **WskBind**.

The following code example shows how a WSK application can bind a listening socket to a local transport address.

```
C++

// Prototype for the bind IoCompletion routine
NTSTATUS
  BindComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to bind a listening socket to a local transport address
NTSTATUS
  BindListeningSocket(
    PWSK_SOCKET Socket,
    PSOCKADDR LocalAddress
    )
{
  PWSK_PROVIDER_LISTEN_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_LISTEN_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    BindComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the bind operation on the socket
  Status =
    Dispatch->WskBind(
      Socket,
      LocalAddress,
      0,  // No flags
      Irp
      );

  // Return the status of the call to WskBind()
  return Status;
}

// Bind IoCompletion routine
NTSTATUS
  BindComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;

  // Check the result of the bind operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

For connection-oriented sockets, a WSK application can call the **WskSocketConnect** function to create, bind, and connect a socket in a single function call.

Listening for and Accepting Incoming Connections

Article • 12/15/2021

After a Winsock Kernel (WSK) application binds a listening socket to a local transport address, the socket begins listening for incoming connections from remote transport addresses. A WSK application can accept an incoming connection on a listening socket by calling the WskAccept function. The IRP that the application passes to the **WskAccept** function is queued until an incoming connection arrives.

The following code example shows how a WSK application can accept an incoming connection by calling the **WskAccept** function.

```C++
// Prototype for the accept IoCompletion routine
NTSTATUS
  AcceptComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to accept an incoming connection
NTSTATUS
  AcceptConnection(
    PWSK_SOCKET Socket,
    PVOID AcceptSocketContext,
    PWSK_CLIENT_CONNECTION_DISPATCH AcceptSocketDispatch
    )
{
  PWSK_PROVIDER_LISTEN_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_LISTEN_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    AcceptComplete,
    AcceptSocketContext,
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the accept operation on the socket
  Status =
    Dispatch->WskAccept(
      Socket,
      0,  // No flags
      AcceptSocketContext,
      AcceptSocketDispatch,
      NULL,
      NULL,
      Irp
      );

  // Return the status of the call to WskAccept()
  return Status;
}

// The accept IoCompletion routine
NTSTATUS
  AcceptComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;
  PVOID AcceptSocketContext;

  // Check the result of the accept operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the accepted socket object from the IRP
    Socket = (PWSK_SOCKET)(Irp->IoStatus.Information);

    // Get the accepted socket's context
    AcceptSocketContext = Context;

    // Perform the next operation on the accepted socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

As an alternative to calling the **WskAccept** function to accept incoming connections on a listening socket, a WSK application can enable the *WskAcceptEvent* event callback function on the socket. If a WSK application enables the *WskAcceptEvent* event callback function on a listening socket, the WSK subsystem calls the socket's *WskAcceptEvent* event callback function whenever a new incoming connection is accepted on the socket. For more information about enabling a listening socket's *WskAcceptEvent* event callback function, see Enabling and Disabling Event Callback Functions.

The following code example shows how a WSK application can accept an incoming connection by the WSK subsystem calling a listening socket's *WskAcceptEvent* event callback function.

C++

```
// Dispatch table of event callback functions for accepted sockets
const WSK_CLIENT_CONNECTION_DISPATCH ConnectionDispatch =
{
  .
  . // Function pointers for the event callback functions
  .
};

// Pool tag used for allocating the socket context
#define SOCKET_CONTEXT_POOL_TAG 'tpcs'

// A listening socket's WskAcceptEvent event callback function
NTSTATUS WSKAPI
  WskAcceptEvent(
    PVOID SocketContext,
    ULONG Flags,
    PSOCKADDR LocalAddress,
    PSOCKADDR RemoteAddress,
    PWSK_SOCKET AcceptSocket,
    PVOID *AcceptSocketContext,
    CONST WSK_CLIENT_CONNECTION_DISPATCH **AcceptSocketDispatch
    )
{
  PWSK_APP_SOCKET_CONTEXT SocketContext;

  // Check for a valid new socket
  if (AcceptSocket != NULL)
  {
    // Allocate the socket context
    SocketContext =
      (PWSK_APP_SOCKET_CONTEXT)
        ExAllocatePoolWithTag(
          NonPagedPool,
          sizeof(WSK_APP_SOCKET_CONTEXT),
          SOCKET_CONTEXT_POOL_TAG
          );

    // Check result of allocation
    if (SocketContext == NULL)
    {
      // Reject the socket
      return STATUS_REQUEST_NOT_ACCEPTED;
    }

    // Initialize the socket context
    SocketContext->Socket = AcceptSocket;
    ...

    // Set the accepted socket's client context
    *AcceptSocketContext = SocketContext;

    // Set the accepted socket's dispatch table of callback functions
    *AcceptSocketDispatch = ConnectionDispatch;

    // Perform additional operations on the accepted socket
    ...

    // Return status indicating that the socket was accepted
    return STATUS_SUCCESS:
  }

  // Error with listening socket
  else
  {
    // Handle error
    ...

    // Return status indicating that no socket was accepted
    return STATUS_REQUEST_NOT_ACCEPTED;
  }
}
```

A WSK application can configure a listening socket to conditionally accept incoming connections that are received on the socket. A WSK application enables conditional accept mode on a listening socket by setting the **SO_CONDITIONAL_ACCEPT** socket option for the socket prior to binding the socket to a local transport address. For more information about how to set socket options, see Performing Control Operations on a Socket.

If conditional accept mode is enabled on a listening socket, the WSK subsystem first calls the socket's *WskInspectEvent* event callback function whenever a new incoming connection request is received on the socket. A socket's *WskInspectEvent* event callback function can inspect the incoming connection request to determine if the request should be accepted or rejected. To accept the request, the socket's *WskInspectEvent* event callback function returns **InspectAccept**. To reject the request, the socket's *WskInspectEvent* event callback function returns **InspectReject**. If a socket's *WskInspectEvent* event callback function cannot immediately determine if the request should be accepted or rejected, it returns **InspectPend**. In this situation, a WSK application must call the **WskInspectComplete** function after completing the inspection process for the incoming connection request. If an incoming connection request is dropped before the socket connection is fully established, the WSK subsystem calls the WSK application's *WskAbortEvent* event callback function.

The following code example shows how a WSK application can inspect an incoming connection request by the WSK subsystem calling the listening socket's *WskInspectEvent* event callback function.

C++

```
// Inspect ID for a pending inspection
WSK_INSPECT_ID PendingInspectID

// A listening socket's WskInspectEvent event callback function
WSK_INSPECT_ACTION WSKAPI
  WskInspectEvent(
    PVOID SocketContext,
    PSOCKADDR LocalAddress,
    PSOCKADDR RemoteAddress,
    PWSK_INSPECT_ID InspectID
    )
{
  // Check for a valid inspect ID
  if (InspectID != NULL)
  {
    // Inspect local and/or remote address of the incoming
    // connection request to determine if the connection should
    // be accepted or rejected.
    ...
    // If the incoming connection should be accepted
    if (...)
    {
      // Return status indicating that the incoming
      // connection request was accepted
      return InspectAccept;
    }

    // If the incoming connection should be rejected
    else if (...)
    {
      // Return status indicating that the incoming
      // connection request was rejected
      return InspectReject;
    }

    // Cannot determine immediately
    else
    {
      // Save the inspect ID while the inspection is pending.
      // This will be passed to WskInspectComplete when the
      // inspection process is completed.
      PendingInspectID = *InspectID;

      // Return status indicating that the result of the
      // inspection process for the incoming connection
      // request is pending
      return InspectPend;
    }
  }

  // Error with listening socket
  else
  {
    // Handle error
    ...

    // Return status indicating that a socket was not accepted
    return InspectReject;
  }
}

// A listening socket's WskAbortEvent event callback function
NTSTATUS WSKAPI
  WskAbortEvent(
    PVOID SocketContext,
    PWSK_INSPECT_ID InspectID
    )
{
  // Terminate the inspection for the incoming connection
  // request with a matching inspect ID. To test for a matching
  // inspect ID, the contents of the WSK_INSPECT_ID structures
  // must be compared, not the pointers to the structures.
  ...
}
```

If a WSK application determines that it will accept an incoming connection request on a listening socket that has conditional accept mode enabled, the incoming connection will be established and it can be accepted normally by either the application calling to the **WskAccept** function or the WSK subsystem calling the socket's *WskAcceptEvent* event callback function as described previously.

Establishing a Connection with a Destination

Article • 12/15/2021

After a Winsock Kernel (WSK) application has bound a connection-oriented socket to a local transport address, it can connect the socket to a remote transport address in order to establish a connection with the remote system. A WSK application must connect a connection-oriented socket to a remote transport address before it can send or receive data over the socket.

A WSK application connects a socket to a remote transport address by calling the WskConnect function. The **WskConnect** function is pointed to by the **WskConnect** member of the socket's provider dispatch structure. A socket's provider dispatch structure is pointed to by the **Dispatch** member of the socket object structure (WSK_SOCKET) that was returned by the WSK subsystem during the creation of the socket.

The following code example shows how a WSK application can connect a connection-oriented socket to a remote transport address.

C++

```
// Prototype for the connect IoCompletion routine
NTSTATUS
  ConnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to connect a socket to a remote transport address
NTSTATUS
  ConnectSocket(
    PWSK_SOCKET Socket,
    PSOCKADDR RemoteAddress
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ConnectComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the connect operation on the socket
  Status =
    Dispatch->WskConnect(
      Socket,
      RemoteAddress,
      0,  // No flags
      Irp
      );

  // Return the status of the call to WskConnect()
  return Status;
}

// Connect IoCompletion routine
NTSTATUS
  ConnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;

  // Check the result of the connect operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

A WSK application can call the **WskSocketConnect** function to create, bind, and connect a connection-oriented socket in a single function call.

Sending and receiving data over WSK sockets

Article • 12/15/2021

This section discusses sending and receiving data over Winsock Kernel (WSK) sockets and includes the following sections:

- Sending Data over a Datagram Socket
- Receiving Data over a Datagram Socket
- Sending Data over a Connection-Oriented Socket
- Receiving Data over a Connection-Oriented Socket

Sending Data over a Datagram Socket

Article • 12/15/2021

After a Winsock Kernel (WSK) application has bound a datagram socket to a local transport address it can send datagrams over the socket. A WSK application sends a datagram over a datagram socket by calling the **WskSendTo** function.

The following code example shows how a WSK application can send a datagram over a datagram socket.

```C++
// Prototype for the send datagram IoCompletion routine
NTSTATUS
  SendDatagramComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to send a datagram
NTSTATUS
  SendDatagram(
    PWSK_SOCKET Socket,
    PWSK_BUF DatagramBuffer,
    PSOCKADDR RemoteAddress
    )
{
  PWSK_PROVIDER_DATAGRAM_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_DATAGRAM_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }
  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    SendDatagramComplete,
    DatagramBuffer,  // Use the datagram buffer for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the send operation on the socket
  Status =
    Dispatch->WskSendTo(
      Socket,
      DatagramBuffer,
      0,  // No flags
      RemoteAddress,
      0,
      NULL,  // No associated control info
      Irp
      );

  // Return the status of the call to WskSendTo()
  return Status;
}

// Send datagram IoCompletion routine
NTSTATUS
  SendDatagramComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DatagramBuffer;
  ULONG ByteCount;

  // Check the result of the send operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the datagram buffer
    DatagramBuffer = (PWSK_BUF)Context;

    // Get the number of bytes sent
    ByteCount = (ULONG)(Irp->IoStatus.Information);

    // Re-use or free the datagram buffer
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

If the WSK application has set either a fixed remote transport address or a fixed destination transport address for the datagram socket, the *RemoteAddress* parameter passed to the **WskSendTo** function is optional and can be **NULL**. If **NULL**, the datagram is sent to the fixed remote transport address or the fixed destination transport address. If non-**NULL**, the datagram is sent to the specified remote transport address.

For more information about setting a fixed remote transport address for a datagram socket, see SIO_WSK_SET_REMOTE_ADDRESS.

For more information about setting a fixed destination transport address for a datagram socket, see SIO_WSK_SET_SENDTO_ADDRESS.

Receiving Data over a Datagram Socket

Article • 12/15/2021

After a Winsock Kernel (WSK) application has bound a datagram socket to a local transport address it can receive datagrams over the socket. A WSK application receives a datagram over a datagram socket by calling the **WskReceiveFrom** function.

The following code example shows how a WSK application can receive a datagram over a datagram socket.

C++

```C++
// Prototype for the receive datagram IoCompletion routine
NTSTATUS
  ReceiveDatagramComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to receive a datagram
NTSTATUS
  ReceiveDatagram(
    PWSK_SOCKET Socket,
    PWSK_BUF DatagramBuffer
    )
{
  PWSK_PROVIDER_DATAGRAM_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_DATAGRAM_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ReceiveDatagramComplete,
    DatagramBuffer,  // Use the datagram buffer for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the receive operation on the socket
  Status =
    Dispatch->WskReceiveFrom(
      Socket,
      DatagramBuffer,
      0,  // No flags are specified
      NULL,  // Not interested in the remote address
      NULL,  // Not interested in any associated control information
      NULL,
      NULL,
      Irp
      );

  // Return the status of the call to WskReceiveFrom()
  return Status;
}

// Receive datagram IoCompletion routine
NTSTATUS
  ReceiveDatagramComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DataBuffer;
  ULONG ByteCount;

  // Check the result of the receive operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the data buffer
    DataBuffer = (PWSK_BUF)Context;

    // Get the number of bytes received
    ByteCount = (ULONG)(Irp->IoStatus.Information);

    // Process the received datagram
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

As an alternative to calling the **WskReceiveFrom** function to receive each datagram over a datagram socket, a WSK application can enable the *WskReceiveFromEvent* event callback function on the socket. If a WSK application enables the *WskReceiveFromEvent* event callback function on a datagram socket, the WSK subsystem calls the socket's *WskReceiveFromEvent* event callback function whenever new datagrams are received on the socket. For more information about enabling a datagram socket's *WskReceiveFromEvent* event callback function, see Enabling and Disabling Event Callback Functions.

The following code example shows how a WSK application can receive datagrams by the WSK subsystem by calling a datagram socket's *WskReceiveFromEvent* event callback function.

C++

```
// A datagram socket's WskReceiveFromEvent
// event callback function
NTSTATUS WSKAPI
  WskReceiveFromEvent(
    PVOID SocketContext,
    ULONG Flags,
    PWSK_DATAGRAM_INDICATION DataIndication
    )
{
  // Check for a valid data indication
  if (DataIndication != NULL)
  {
    // Loop through the list of data indication structures
    while (DataIndication != NULL)
    {
      // Process the data in the data indication structure
      ...

      // Move to the next data indication structure
      DataIndication = DataIndication->Next;
    }

    // Return status indicating the datagrams were received
    return STATUS_SUCCESS;
  }

  // Error
  else
  {
    // Close the socket
    ...

    // Return success since no datagrams were indicated
    return STATUS_SUCCESS;
  }
}
```

If a datagram socket's *WskReceiveFromEvent* event callback function does not retrieve all of the datagrams from the list of **WSK_DATAGRAM_INDICATION** structures pointed to by the *DataIndication* parameter, it can retain the list for further processing by returning STATUS_PENDING. In this situation, the WSK application must call the **WskRelease** function to release the list of WSK_DATAGRAM_INDICATION structures back to the WSK subsystem after it has completed retrieving all of the datagrams from the structures in the list.

Sending Data over a Connection-Oriented Socket

Article • 12/15/2021

After a Winsock Kernel (WSK) application has connected a connection-oriented socket to a remote transport address it can send data over the socket. A WSK application can also send data over a connection-oriented socket that it accepted on a listening socket. A WSK application sends data over a connection-oriented socket by calling the **WskSend** function.

The following code example shows how a WSK application can send data over a connection-oriented socket.

```C++
// Prototype for the send IoCompletion routine
NTSTATUS
  SendComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to send data
NTSTATUS
  SendData(
    PWSK_SOCKET Socket,
    PWSK_BUF DataBuffer
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    SendComplete,
    DataBuffer,  // Use the data buffer for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the send operation on the socket
  Status =
    Dispatch->WskSend(
      Socket,
      DataBuffer,
      0,  // No flags
      Irp
      );

  // Return the status of the call to WskSend()
  return Status;
}

// Send IoCompletion routine
NTSTATUS
  SendComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DataBuffer;
  ULONG ByteCount;

  // Check the result of the send operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the data buffer
    DataBuffer = (PWSK_BUF)Context;

    // Get the number of bytes sent
    ByteCount = (ULONG)(Irp->IoStatus.Information);

    // Re-use or free the data buffer
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

Receiving Data over a Connection-Oriented Socket

Article • 12/15/2021

After a Winsock Kernel (WSK) application has connected a connection-oriented socket to a remote transport address it can receive data over the socket. A WSK application can also receive data over a connection-oriented socket that it accepted on a listening socket. A WSK application receives data over a connection-oriented socket by calling the **WskReceive** function.

The following code example shows how a WSK application can receive data over a connection-oriented socket.

C++

```cpp
// Prototype for the receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to receive data
NTSTATUS
  ReceiveData(
    PWSK_SOCKET Socket,
    PWSK_BUF DataBuffer
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    ReceiveComplete,
    DataBuffer,  // Use the data buffer for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the receive operation on the socket
  Status =
    Dispatch->WskReceive(
      Socket,
      DataBuffer,
      0,  // No flags are specified
      Irp
      );

  // Return the status of the call to WskReceive()
  return Status;
}

// Receive IoCompletion routine
NTSTATUS
  ReceiveComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_BUF DataBuffer;
  ULONG ByteCount;

  // Check the result of the receive operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the data buffer
    DataBuffer = (PWSK_BUF)Context;

    // Get the number of bytes received
    ByteCount = (ULONG)(Irp->IoStatus.Information);

    // Process the received data
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

As an alternative to calling the **WskReceive** function to receive data over a connection-oriented socket, a WSK application can enable the *WskReceiveEvent* event callback function on the socket. If a WSK application enables the *WskReceiveEvent* event callback function on a connection-oriented socket, the WSK subsystem calls the socket's *WskReceiveEvent* event callback function whenever new data is received on the socket. For more information about enabling a connection-oriented socket's *WskReceiveEvent* event callback function, see Enabling and Disabling Event Callback Functions.

The following code example shows how a WSK application can receive data by the WSK subsystem calling a connection-oriented socket's *WskReceiveEvent* event callback function.

C++

```
// A connection-oriented socket's WskReceiveEvent
// event callback function
NTSTATUS WSKAPI
  WskReceiveEvent(
    PVOID SocketContext,
    ULONG Flags,
    PWSK_DATA_INDICATION DataIndication,
    SIZE_T BytesIndicated,
    SIZE_T *BytesAccepted
    )
{
  // Check for a valid data indication
  if (DataIndication != NULL)
  {
    // Loop through the list of data indication structures
    while (DataIndication != NULL)
    {
      // Process the data in the data indication structure
      ...

      // Move to the next data indication structure
      DataIndication = DataIndication->Next;
    }
    // Return status indicating the data was received
    return STATUS_SUCCESS;
  }

  // Error
  else
  {
    // Close the socket
    ...

    // Return success since no data was indicated
    return STATUS_SUCCESS;
  }
}
```

If a connection-oriented socket's *WskReceiveEvent* event callback function does not retrieve all of the data contained in the list of **WSK_DATA_INDICATION** structures pointed to by the *DataIndication* parameter, it can retain the list for further processing by returning STATUS_PENDING. In this situation, the WSK application must call the **WskRelease** function to release the list of WSK_DATA_INDICATION structures back to the WSK subsystem after it has completed retrieving all of the data from the structures in the list.

If a connection-oriented socket's *WskReceiveEvent* event callback function only accepts a portion of the total number of bytes of received data, it must set the variable pointed to by the *BytesAccepted* parameter to the number of bytes of data that were actually accepted. However, if the socket's *WskReceiveEvent* event callback function accepts all of the received data, it does not need to set the variable pointed to by the *BytesAccepted* parameter.

Disconnecting a Socket from a Destination

Article • 12/15/2021

When a Winsock Kernel (WSK) application has finished sending and receiving data over an established socket connection, it can disconnect the connection-oriented socket from the remote transport address to which it is connected. A WSK application disconnects a socket from a remote transport address by calling the **WskDisconnect** function. A WSK application can perform either an *abortive disconnect* or a *graceful disconnect* of the socket. For more information about the difference between an abortive disconnect and a graceful disconnect, see **WskDisconnect**.

The following code example shows how a WSK application can gracefully disconnect a connection-oriented socket from a remote transport address.

C++

```
// Prototype for the disconnect IoCompletion routine
NTSTATUS
  DisconnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to disconnect a socket from a remote transport address
NTSTATUS
  DisconnectSocket(
    PWSK_SOCKET Socket
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    DisconnectComplete,
    Socket,  // Use the socket object for the context
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the disconnect operation on the socket
  Status =
    Dispatch->WskDisconnect(
      Socket,
      NULL,  // No final data to be transmitted
      0,     // No flags (graceful disconnect)
      Irp
      );

  // Return the status of the call to WskDisconnect()
  return Status;
}

// Disconnect IoCompletion routine
NTSTATUS
  DisconnectComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_SOCKET Socket;

  // Check the result of the disconnect operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the socket object from the context
    Socket = (PWSK_SOCKET)Context;

    // Perform the next operation on the socket
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

If a WSK application performs a graceful disconnect of a socket, the application can send a final buffer of data to the remote transport address before the socket is disconnected by passing a pointer to a **WSK_BUF** structure to the **WskDisconnect** function.

If a WSK application closes a connection-oriented socket without first disconnecting the socket from the remote transport address to which it is connected, the WSK subsystem automatically performs an abortive disconnect of the socket prior to closing the socket. For more information about closing a socket, see Closing a Socket.

Closing a Socket

Article • 12/15/2021

When a Winsock Kernel (WSK) application has finished using a socket, it should close the socket and free up any associated resources. A WSK application must close all open sockets before the application can detach itself from the WSK subsystem. For more information about detaching a WSK application from the WSK subsystem, see Unregistering a Winsock Kernel Application.

A WSK application closes a socket by calling the **WskCloseSocket** function. Before calling the **WskCloseSocket** function, a WSK application must ensure that there are no other function calls in progress to any of the socket's functions, including any extension functions in any of the application's other threads. However, a WSK application can call **WskCloseSocket** if there are pending IRPs from prior calls to the socket's functions that have not yet completed.

The method that a WSK application uses to ensure that there are no other function calls in progress to any of the socket's functions before it calls the **WskCloseSocket** function is dependent upon the design of the application. For example, if a WSK application might need to close a socket in one thread while there could be calls in progress to that socket's other functions in one or more other threads, then the application would typically use a reference counter to track the number of function calls that are currently in progress on the socket. In this situation, the WSK application atomically tests and increments a socket's reference counter before it calls one of the socket's functions, and then atomically decrements the socket's reference counter when the function returns. When the reference counter is zero, the WSK application can safely call the **WskCloseSocket** function to close the socket.

On the other hand, if the design of the WSK application guarantees that there will not be any calls in progress to a particular socket's functions in any other threads when the application calls the **WskCloseSocket** function to close the socket, then the WSK application does not need to use a reference counter to track the number of function calls that are currently in progress on the socket. For example, if the WSK application performs all of its socket operations for a particular socket from a single thread, then the application can safely call the **WskCloseSocket** function from within that thread without the need for a reference counter.

Calling the **WskCloseSocket** function causes the WSK subsystem to cancel and complete all pending IRPs from prior calls to the socket's functions. The WSK subsystem also ensures that any event callback functions in progress have returned control back to the WSK subsystem before the close operation is completed.

The following code example shows how a WSK application can close a socket.

```C++
// Prototype for the socket close IoCompletion routine
NTSTATUS
  CloseSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    );

// Function to close a socket
NTSTATUS
  CloseSocket(
    PWSK_SOCKET Socket,
    PWSK_APP_SOCKET_CONTEXT SocketContext
    )
{
  PWSK_PROVIDER_BASIC_DISPATCH Dispatch;
  PIRP Irp;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_BASIC_DISPATCH)(Socket->Dispatch);

  // Allocate an IRP
  Irp =
    IoAllocateIrp(
      1,
      FALSE
      );

  // Check result
  if (!Irp)
  {
    // Return error
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Set the completion routine for the IRP
  IoSetCompletionRoutine(
    Irp,
    CloseSocketComplete,
    SocketContext,
    TRUE,
    TRUE,
    TRUE
    );

  // Initiate the close operation on the socket
  Status =
    Dispatch->WskCloseSocket(
      Socket,
      Irp
      );

  // Return the status of the call to WskCloseSocket()
  return Status;
}

// Socket close IoCompletion routine
NTSTATUS
  CloseSocketComplete(
    PDEVICE_OBJECT DeviceObject,
    PIRP Irp,
    PVOID Context
    )
{
  UNREFERENCED_PARAMETER(DeviceObject);

  PWSK_APP_SOCKET_CONTEXT SocketContext;

  // Check the result of the socket close operation
  if (Irp->IoStatus.Status == STATUS_SUCCESS)
  {
    // Get the pointer to the socket context
    SocketContext =
      (PWSK_APP_SOCKET_CONTEXT)Context;

    // Perform any cleanup and/or deallocation of the socket context
    ...
  }

  // Error status
  else
  {
    // Handle error
    ...
  }

  // Free the IRP
  IoFreeIrp(Irp);

  // Always return STATUS_MORE_PROCESSING_REQUIRED to
  // terminate the completion processing of the IRP.
  return STATUS_MORE_PROCESSING_REQUIRED;
}
```

After a WSK application has called WskCloseSocket, it should not make any further calls to any of the socket's functions.

If a WSK application closes a connection-oriented socket that has not been previously disconnected in both directions, the WSK subsystem automatically performs an abortive disconnect of the socket before closing the socket. For more information about disconnecting a socket, see Disconnecting a Socket from a Destination.

Registering an Extension Interface

Article • 12/15/2021

After a Winsock Kernel (WSK) application has successfully created a socket, it can register that socket for one or more of the extension interfaces that are supported by the WSK subsystem. A WSK application determines which set of extension interfaces are supported by the WSK subsystem by examining the **Version** member of the **WSK_PROVIDER_DISPATCH** structure that the WSK subsystem returned to the application during attachment.

Each extension interface is defined by an NPI that is independent of the WSK NPI. Note, however, that the NPIs for extension interfaces do not support NPI-specific characteristics.

A WSK application registers for an extension interface by executing the **SIO_WSK_REGISTER_EXTENSION** socket IOCTL operation on the socket. For more information about executing socket IOCTL operations, see Performing Control Operations on a Socket.

If a WSK application attempts to register a socket for an extension interface that is not supported by the WSK subsystem, the SIO_WSK_REGISTER_EXTENSION socket IOCTL operation will return STATUS_NOT_SUPPORTED.

For example, suppose that an extension interface is defined as in the following code example.

```C++
const NPIID EXAMPLE_EXTIF_NPIID = {...};

typedef struct _EXAMPLE_EXTIF_PROVIDER_DISPATCH {
  .
  . // Function pointers for the functions that are
  . // defined by the extension interface.
  .
} EXAMPLE_EXTIF_PROVIDER_DISPATCH, *PEXAMPLE_EXTIF_PROVIDER_DISPATCH;

typedef struct _EXAMPLE_EXTIF_CLIENT_DISPATCH {
  .
  . // Function pointers for the callback functions
  . // that are defined by the extension interface.
  .
} EXAMPLE_EXTIF_CLIENT_DISPATCH, *PEXAMPLE_EXTIF_CLIENT_DISPATCH;
```

The following shows how a WSK application can register for this extension interface for a connection-oriented socket.

C++

```
// Client dispatch structure for the extension interface
const EXAMPLE_EXTIF_CLIENT_DISPATCH ExtIfClientDispatch = {
  .
  . // The WSK application's callback functions
  . // for the extension interface
  .
};

// Context structure type for the example extension interface
typedef struct _EXAMPLE_EXTIF_CLIENT_CONTEXT
{
  const EXAMPLE_EXTIF_PROVIDER_DISPATCH *ExtIfProviderDispatch;
  PVOID ExtIfProviderContext;
    .
    .  // Other application-specific members
    .
} EXAMPLE_EXTIF_CLIENT_CONTEXT, *PEXAMPLE_EXTIF_CLIENT_CONTEXT;

// Function to register the example extension interface
NTSTATUS
  RegisterExampleExtIf(
    PWSK_SOCKET Socket,
    PEXAMPLE_EXTIF_CLIENT_CONTEXT ExtIfClientContext
    )
{
  PWSK_PROVIDER_CONNECTION_DISPATCH Dispatch;
  WSK_EXTENSION_CONTROL_IN ExtensionControlIn;
  WSK_EXTENSION_CONTROL_OUT ExtensionControlOut;
  NTSTATUS Status;

  // Get pointer to the socket's provider dispatch structure
  Dispatch =
    (PWSK_PROVIDER_CONNECTION_DISPATCH)(Socket->Dispatch);

  // Fill in the WSK_EXTENSION_CONTROL_IN structure
  ExtensionControlIn.NpiId = &EXAMPLE_EXTIF_NPIID;
  ExtensionControlIn.ClientContext = ExtIfClientContext;
  ExtensionControlIn.ClientDispatch = &ExtIfClientDispatch;

  // Initiate the IOCTL operation on the socket
  Status =
    Dispatch->WskControlSocket(
      Socket,
      WskIoctl,
      SIO_WSK_REGISTER_EXTENSION,
      0,
      sizeof(WSK_EXTENSION_CONTROL_IN),
      &ExtensionControlIn,
      sizeof(WSK_EXTENSION_CONTROL_OUT),
      &ExtensionControlOut,
      NULL,
      NULL  // No IRP used for this IOCTL operation
      );

  // Check result
  if (Status == STATUS_SUCCESS)
  {
    // Save provider dispatch table and provider context
    ExtIfClientContext->ExtIfProviderDispatch =
      (const EXAMPLE_EXTIF_PROVIDER_DISPATCH *)
        ExtensionControlOut.ProviderDispatch;
    ExtIfClientContext->ExtIfProviderContext =
      ExtensionControlOut.ProviderContext;
  }

  // Return the status of the call to WskControlSocket()
  return Status;
}
```

A WSK application registers for extension interfaces on a socket-by-socket basis.

Unregistering a Winsock Kernel Application

Article • 12/15/2021

A Winsock Kernel (WSK) application that has successfully registered as a WSK client with the WskRegister function must ensure that WskDeregister has been called, and the call has returned, before the driver's Unload function returns. A WSK application that has called **WskRegister** successfully should never unload without calling **WskDeregister**, which will wait to unregister the WSK client object until all captured instances of the WSK provider NPI are released with WskReleaseProviderNPI and all sockets are closed by the WSK application. If there are pending IRPs that were passed to the functions in WSK_PROVIDER_DISPATCH, **WskDeregister** will also wait until those pending IRPs complete. A WSK application should never call the functions in WSK_PROVIDER_DISPATCH after **WskReleaseProviderNPI** is called.

For example:

```C++
// Unload function
VOID
  Unload(
    IN PDRIVER_OBJECT DriverObject
    )
{
  // Unregister the WSK application
  WskDeregister(
    &WskRegistration
    );

}
```

A WSK application is not necessarily required to always call **WskDeregister** from within its *Unload* function. For example, if a WSK application is a subcomponent of a complex driver, the WSK application's call to **WskDeregister** might occur when the WSK application subcomponent is deactivated. In such a scenario, before the driver returns from its *Unload* function, it must still ensure that the WSK application has been successfully unregistered with a call to **WskDeregister**.

Resolving Host Names and IP Addresses

Article • 12/15/2021

Beginning with Windows 7, a *kernel name resolution* feature allows kernel-mode components to perform protocol-independent translation between Unicode host names and transport addresses. You can use the following Winsock Kernel (WSK) client-level functions to perform this name resolution:

- **WskFreeAddressInfo**
- **WskGetAddressInfo**
- **WskGetNameInfo**

These functions perform name-address translation similarly to the user-mode functions **FreeAddrInfoW**, **GetAddrInfoW**, and **GetNameInfoW**, respectively.

To take advantage of this feature, you must compile or recompile your driver with the NTDDI_VERSION macro set to NTDDI_WIN7 or greater.

In order for your driver to use kernel name resolution functionality, it must perform the following calling sequence:

1. Call **WskRegister** to register with WSK.
2. Call **WskCaptureProviderNPI** to capture the WSK provider Network Programming Interface (NPI).
3. When you are done using the WSK provider NPI, call **WskReleaseProviderNPI** to release the WSK provider NPI.
4. Call **WskDeregister** to deregister the WSK application.

The following code example uses the above calling sequence to show how a WSK application can call the **WskGetAddressInfo** function to translate a host name to a transport address.

C++

```
NTSTATUS
SyncIrpCompletionRoutine(
    __in PDEVICE_OBJECT Reserved,
    __in PIRP Irp,
    __in PVOID Context
    )
{
    PKEVENT compEvent = (PKEVENT)Context;
    UNREFERENCED_PARAMETER(Reserved);
    UNREFERENCED_PARAMETER(Irp);
    KeSetEvent(compEvent, 2, FALSE);
    return STATUS_MORE_PROCESSING_REQUIRED;
}

NTSTATUS
KernelNameResolutionSample(
    __in PCWSTR NodeName,
    __in_opt PCWSTR ServiceName,
    __in_opt PADDRINFOEXW Hints,
    __in PWSK_PROVIDER_NPI WskProviderNpi
    )
{
    NTSTATUS status;
    PIRP irp;
    KEVENT completionEvent;
    UNICODE_STRING uniNodeName, uniServiceName, *uniServiceNamePtr;
    PADDRINFOEXW results;

    PAGED_CODE();
    //
    // Initialize UNICODE_STRING structures for NodeName and ServiceName
    //

    RtlInitUnicodeString(&uniNodeName, NodeName);

    if(ServiceName == NULL) {
        uniServiceNamePtr = NULL;
    }
    else {
        RtlInitUnicodeString(&uniServiceName, ServiceName);
        uniServiceNamePtr = &uniServiceName;
    }

    //
    // Use an event object to synchronously wait for the
    // WskGetAddressInfo request to be completed.
    //

    KeInitializeEvent(&completionEvent, SynchronizationEvent, FALSE);

    //
    // Allocate an IRP for the WskGetAddressInfo request, and set the
    // IRP completion routine, which will signal the completionEvent
    // when the request is completed.
    //

    irp = IoAllocateIrp(1, FALSE);
    if(irp == NULL) {
        return STATUS_INSUFFICIENT_RESOURCES;
    }

    IoSetCompletionRoutine(irp, SyncIrpCompletionRoutine,
  &completionEvent, TRUE, TRUE, TRUE);

    //
    // Make the WskGetAddressInfo request.
    //

    WskProviderNpi->Dispatch->WskGetAddressInfo (
        WskProviderNpi->Client,
        &uniNodeName,
        uniServiceNamePtr,
        NS_ALL,
        NULL, // Provider
        Hints,
        &results,
        NULL, // OwningProcess
        NULL, // OwningThread
        irp);

    //
    // Wait for completion. Note that processing of name resolution results
    // can also be handled directly within the IRP completion routine, but
    // for simplicity, this example shows how to wait synchronously for
    // completion.
    //

    KeWaitForSingleObject(&completionEvent, Executive,
                        KernelMode, FALSE, NULL);

    status = irp->IoStatus.Status;

    IoFreeIrp(irp);

    if(!NT_SUCCESS(status)) {
        return status;
    }

    //
    // Process the name resolution results by iterating through the
addresses
    // within the returned ADDRINFOEXW structure.
    //

   results; // your code here

    //
    // Release the returned ADDRINFOEXW structure when no longer needed.
    //

    WskProviderNpi->Dispatch->WskFreeAddressInfo(
        WskProviderNpi->Client,
        results);

    return status;
}
```

WSK_CACHE_SD

Article • 03/03/2023

A WSK application uses the WSK_CACHE_SD client control operation to obtain a cached copy of a security descriptor that can be passed to the WskSocket, WskSocketConnect, and WskControlSocket functions.

To obtain a cached copy of a security descriptor, a WSK application calls the WskControlClient function with the following parameters.

Parameter	Value
ControlCode	WSK_CACHE_SD
InputSize	sizeof(PSECURITY_DESCRIPTOR)
InputBuffer	A pointer to a PSECURITY_DESCRIPTOR-typed variable. This variable contains a pointer to the SECURITY_DESCRIPTOR structure that defines the uncached security descriptor that is being cached.
OutputSize	sizeof(PSECURITY_DESCRIPTOR)
OutputBuffer	A pointer to a PSECURITY_DESCRIPTOR-typed variable. This variable receives a pointer to a SECURITY_DESCRIPTOR structure that describes the cached security descriptor.
OutputSizeReturned	**NULL**
Irp	**NULL**

A WSK application must release the cached copy of the security descriptor by using the WSK_RELEASE_SD client control operation when the security descriptor is no longer needed.

See the reference page for the SECURITY_DESCRIPTOR structure for more information.

The *Irp* parameter must be **NULL** for this client control operation.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Wsk.h (include Wsk.h)

WSK_RELEASE_SD

Article • 03/03/2023

A WSK application uses the WSK_RELEASE_SD client control operation to release a cached copy of a security descriptor that either was previously obtained by using the WSK_CACHE_SD client control operation or was retrieved by using the SO_WSK_SECURITY socket option.

To release a cached copy of a security descriptor, a WSK application calls the WskControlClient function with the following parameters.

Parameter	Value
ControlCode	WSK_RELEASE_SD
InputSize	sizeof(PSECURITY_DESCRIPTOR)
InputBuffer	A pointer to a PSECURITY_DESCRIPTOR-typed variable. This variable contains a pointer to the SECURITY_DESCRIPTOR structure that defines the cached security descriptor that is being released.
OutputSize	0
OutputBuffer	**NULL**
OutputSizeReturned	**NULL**
Irp	**NULL**

See the reference page for the SECURITY_DESCRIPTOR structure for more information.

The *Irp* parameter must be **NULL** for this client control operation.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_SET_STATIC_EVENT_CALLBACKS

Article • 03/03/2023

A WSK application uses the WSK_SET_STATIC_EVENT_CALLBACKS client control operation to automatically enable certain event callback functions on every socket that it creates. The event callback functions that are enabled in this manner are always enabled and cannot be disabled or re-enabled later by the WSK application. However, if a WSK application always enables certain event callback functions on every socket that it creates, the application should use this method to automatically enable those event callback functions because it will yield much better performance.

If a WSK application uses the WSK_SET_STATIC_EVENT_CALLBACKS client control operation, it must do so before it creates any sockets.

To automatically enable certain event callback functions on every socket it creates, a WSK application calls the **WskControlClient** function with the following parameters.

Parameter	Value
ControlCode	WSK_SET_STATIC_EVENT_CALLBACKS
InputSize	sizeof(WSK_EVENT_CALLBACK_CONTROL)
InputBuffer	A pointer to a **WSK_EVENT_CALLBACK_CONTROL** structure that specifies the desired event callback functions to be automatically enabled
OutputSize	0
OutputBuffer	**NULL**
OutputSizeReturned	**NULL**
Irp	**NULL**

A WSK application can specify a combination of event flags for different socket types in the **EventMask** member of the **WSK_EVENT_CALLBACK_CONTROL** structure. When the WSK application creates a new socket, the WSK subsystem will automatically enable the appropriate event callback functions for the specific category of WSK socket that is being created.

For more information about the event flags for the standard WSK event callback functions, see **SO_WSK_EVENT_CALLBACK**.

For more information about enabling and disabling a socket's event callback functions, see Enabling and Disabling Event Callback Functions.

The *Irp* parameter must be **NULL** for this client control operation.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_TDI_BEHAVIOR

Article • 03/03/2023

Note The TDI feature is deprecated and will be removed in future versions of Microsoft Windows.

A WSK application uses the WSK_TDI_BEHAVIOR client control operation to control whether the WSK subsystem will divert network I/O to TDI transports. A WSK application uses this client control operation only if it needs to override the default behavior of the WSK subsystem.

If a WSK application uses the WSK_TDI_BEHAVIOR client control operation, it must do so before it creates any sockets.

To control whether the WSK subsystem will divert network I/O to TDI transports, a WSK application calls the **WskControlClient** function with the following parameters.

Parameter	Value
ControlCode	WSK_TDI_BEHAVIOR
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG typed variable that contains flags that control the behavior of the WSK subsystem.
OutputSize	0
OutputBuffer	**NULL**
OutputSizeReturned	**NULL**
Irp	**NULL**

The following flags are defined for the WSK_TDI_BEHAVIOR client control operation.

WSK_TDI_BEHAVIOR_BYPASS_TDI
If a native WSK transport exists for the address family, socket type, and protocol that are specified when the WSK application creates a socket, then, if this flag is set, the WSK subsystem ignores any TDI filter drivers and always uses the native WSK transport.

The default behavior is that if a TDI filter driver is detected for the address family, socket type, and protocol that are specified when the WSK application creates a new socket, the WSK subsystem diverts the network I/O for the new socket to the TDI transport so that the network traffic and other socket operations pass through the TDI filter driver.

The *Irp* parameter must be **NULL** for this client control operation.

Note TDI is not supported in Microsoft Windows versions after Windows Vista.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_TDI_DEVICENAME_MAPPING

Article • 03/03/2023

A WSK application uses the WSK_TDI_DEVICENAME_MAPPING client control operation to map combinations of address family, socket type, and protocol to device names of TDI transports. A WSK application uses this client control operation only if it requires support for TDI transports. When a WSK application creates a socket, the WSK subsystem refer to the list of mappings only if there is no native support for the combination of address family, socket type, and protocol specified by the WSK application.

If a WSK application uses the WSK_TDI_DEVICENAME_MAPPING client control operation to map combinations of address family, socket type, and protocol to device names of TDI transports, it must do so before it creates any sockets.

To map combinations of address family, socket type, and protocol to device names of TDI transports, a WSK application calls the **WskControlClient** function with the following parameters.

Parameter	Value
ControlCode	WSK_TDI_DEVICENAME_MAPPING
InputSize	sizeof(WSK_TDI_MAP_INFO)
InputBuffer	A pointer to a **WSK_TDI_MAP_INFO** structure that contains a list of mappings of combinations of address family, socket type, and protocol to TDI device names.
OutputSize	0
OutputBuffer	**NULL**
OutputSizeReturned	**NULL**
Irp	**NULL**

For more information about using TDI transports, see Using TDI Transports.

The *Irp* parameter must be **NULL** for this client control operation.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_TRANSPORT_LIST_CHANGE

Article • 03/03/2023

A WSK application uses the WSK_TRANSPORT_LIST_CHANGE client control operation to receive notification if the list of available network transports changes.

To receive notification of when the list of available network transports changes, a WSK application calls the WskControlClient function with the following parameters.

Parameter	Value
ControlCode	WSK_TRANSPORT_LIST_CHANGE
InputSize	0
InputBuffer	NULL
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL
Irp	A pointer to an IRP that is queued by the WSK subsystem until the list of available network transports changes. The WSK subsystem will complete the IRP after either a new network transport is added or an existing network transport is removed.

An IRP is required for this client control operation.

The WSK subsystem will cancel any pending IRPs if the WSK application calls WskDeregister to detach itself from the WSK subsystem.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_TRANSPORT_LIST_QUERY

Article • 03/03/2023

A WSK application uses the WSK_TRANSPORT_LIST_QUERY client control operation to retrieve a list of available network transports that can be specified when creating a new socket.

To retrieve a list of available network transports, a WSK application calls the WskControlClient function with the following parameters.

Parameter	Value
ControlCode	WSK_TRANSPORT_LIST_QUERY
InputSize	0
InputBuffer	**NULL**
OutputSize	The size, in bytes, of the array of structures that is pointed to by the *OutputBuffer* parameter
OutputBuffer	A pointer to an array of WSK_TRANSPORT structures that receives the list of available network transports
OutputSizeReturned	A pointer to a SIZE_T-typed variable that receives the number of bytes of data that are copied into the array of structures that is pointed to by the *OutputBuffer* parameter
Irp	**NULL**

A WSK application can specify zero in the *OutputSize* parameter and **NULL** in the *OutputBuffer* parameter to determine the size of the array of WSK_TRANSPORT structures, in bytes, that is required to contain the complete list of available network transports. In such a situation, the call to the WskControlClient function returns STATUS_BUFFER_OVERFLOW, and the variable that is pointed to by the *OutputSizeReturned* parameter contains the required buffer size. The application can then allocate a buffer that is large enough to contain the complete list of available network transports and can call the **WskControlClient** function a second time, specifying the parameters that are shown in the preceding table.

The *Irp* parameter must be **NULL** for this client control operation.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_QUERY_IDEAL_SEND_BACKLOG

Article • 03/03/2023

The SIO_WSK_QUERY_IDEAL_SEND_BACKLOG socket I/O control operation allows a WSK application to query the ideal send backlog size for a connection-oriented socket. This socket I/O control operation applies only to connection-oriented sockets.

The ideal send backlog size for a connection-oriented socket is the optimal amount of send data that needs to be kept outstanding (that is, passed to the WSK subsystem but not yet completed) to keep the socket's data stream full at all times. A WSK application can use this size to incrementally probe and lock the buffers of data to be sent based on the underlying connection's flow control state.

If a WSK application uses this socket I/O control operation to query the ideal send backlog size, it must do so after the connection-oriented socket has been connected to a remote transport address.

To query the ideal send backlog size for a connection-oriented socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_QUERY_IDEAL_SEND_BACKLOG
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(SIZE_T)
OutputBuffer	A pointer to a SIZE_T-typed variable that receives the current ideal send backlog size
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to query the ideal send backlog size for a connection-oriented socket.

A connection-oriented socket can be notified of changes to the ideal send backlog size by enabling its *WskSendBacklogEvent* event callback function.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_QUERY_INSPECT_ID

Article • 03/03/2023

The SIO_WSK_QUERY_INSPECT_ID socket I/O control operation allows a WSK application to query the inspection identification data for a connection-oriented socket that has been successfully accepted on a listening socket that has conditional accept mode enabled. This socket I/O control operation applies only to connection-oriented sockets that have been accepted on a listening socket that has conditional accept mode enabled.

To query the inspection identification data for a connection-oriented socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_QUERY_INSPECT_ID
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(WSK_INSPECT_ID)
OutputBuffer	A pointer to a WSK_INSPECT_ID structure that receives the inspection identification data
OutputSizeReturned	A pointer to a ULONG-typed variable that receives the number of bytes of data that is copied into the buffer that is pointed to by the *OutputBuffer* parameter.
Irp	NULL

If a WSK application calls the **WskControlSocket** function to query the inspection identification data for any socket other than a connection-oriented socket that was accepted on a listening socket that has conditional accept mode enabled, the **WskControlSocket** function returns STATUS_INVALID_DEVICE_REQUEST.

For more information about conditionally accepting connections, see Listening for and Accepting Incoming Connections.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_QUERY_RECEIVE_BACKLOG

Article • 03/03/2023

The SIO_WSK_QUERY_RECEIVE_BACKLOG socket I/O control operation allows a WSK application to query the current backlog of received data for a connection-oriented socket. This socket I/O control operation applies only to connection-oriented sockets.

If a WSK application uses this socket I/O control operation to query the receive backlog, it must do so after the connection-oriented socket has been connected to a remote transport address.

To query the current backlog of received data for a connection-oriented socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_QUERY_RECEIVE_BACKLOG
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(SIZE_T)
OutputBuffer	A pointer to a SIZE_T-typed variable that receives the current backlog of received data
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to query the current backlog of received data for a connection-oriented socket.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_REGISTER_EXTENSION

Article • 03/03/2023

The SIO_WSK_REGISTER_EXTENSION socket I/O control operation allows a WSK application to register for an extension interface that is supported by the WSK subsystem. This socket I/O control operation applies to all socket types.

To register an extension interface, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_REGISTER_EXTENSION
Level	0
InputSize	sizeof(WSK_EXTENSION_CONTROL_IN)
InputBuffer	A pointer to a **WSK_EXTENSION_CONTROL_IN** structure. This structure contains a pointer to the Network Programming Interface (NPI) identifier for the extension interface and pointers to the dispatch table and to the context for the WSK application's implementation of the extension interface.
OutputSize	sizeof(WSK_EXTENSION_CONTROL_OUT)
OutputBuffer	A pointer to a **WSK_EXTENSION_CONTROL_OUT** structure. This structure receives a pointer to the dispatch table and a pointer to the context for the WSK subsystem's implementation of the extension interface.
OutputSizeReturned	NULL

A WSK application does not specify a pointer to an IRP when calling the **WskControlSocket** function to register an extension interface.

The contents of the dispatch table structures are extension interface-specific.

For more information about registering an extension interface, see Registering an Extension Interface.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_SET_REMOTE_ADDRESS

Article • 03/03/2023

The SIO_WSK_SET_REMOTE_ADDRESS socket I/O control operation allows a WSK application to specify a fixed remote transport address for a datagram socket. This socket I/O control operation applies only to datagram sockets.

If a WSK application sets a fixed remote transport address for a datagram socket, all datagrams that are sent over the socket are sent to the fixed remote transport address, and only datagrams that are received from the fixed remote transport address are accepted.

A WSK application can override a fixed remote transport address when it sends a datagram over the socket by specifying an alternative remote transport address in the *RemoteAddress* parameter when calling the WskSendTo function. In this situation, the datagram is sent to the alternative remote transport address instead of the fixed remote transport address. However, any responses that are sent back from an alternative remote transport address will not be accepted.

If a WSK application uses this socket I/O control operation to specify a fixed remote transport address, it must do so after the datagram socket has been bound to a local transport address.

To set a fixed remote transport address for a datagram socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_SET_REMOTE_ADDRESS
Level	0
InputSize	The size of the SOCKADDR structure pointed to by the *InputBuffer* parameter.
InputBuffer	A pointer to a structure that specifies a fixed remote transport address for the datagram socket. The pointer must be a pointer to the specific SOCKADDR structure type that corresponds to the address family that the WSK application specified when it created the datagram socket.

Parameter	Value
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To clear a fixed remote transport address for a datagram socket, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_SET_REMOTE_ADDRESS
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or clear a fixed remote transport address for a datagram socket.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_SET_SENDTO_ADDRESS

Article • 03/03/2023

The SIO_WSK_SET_SENDTO_ADDRESS socket I/O control operation allows a WSK application to specify a fixed destination transport address for a datagram socket. This socket I/O control operation applies only to datagram sockets.

If a WSK application sets a fixed destination transport address for a datagram socket, all datagrams that are sent over the socket are sent to the fixed destination transport address. However, datagrams that are received on the socket will be accepted from any transport address.

A WSK application can override a fixed destination transport address when it sends a datagram over the socket by specifying an alternative remote transport address in the *RemoteAddress* parameter when calling the WskSendTo function. In this situation, the datagram is sent to the alternative remote transport address instead of the fixed destination transport address.

If a WSK application uses this socket I/O control operation to specify a fixed destination transport address, it must do so after the datagram socket has been bound to a local transport address.

To set a fixed destination transport address for a datagram socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_SET_SENDTO_ADDRESS
Level	0
InputSize	The size of the SOCKADDR structure that is pointed to by the *InputBuffer* parameter.
InputBuffer	A pointer to a structure that specifies a fixed destination transport address for the datagram socket. The pointer must be a pointer to the specific SOCKADDR structure type that corresponds to the address family that the WSK application specified when it created the datagram socket.
OutputSize	0

Parameter	Value
OutputBuffer	NULL
OutputSizeReturned	NULL

To clear a fixed destination transport address for a datagram socket, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_WSK_SET_SENDTO_ADDRESS
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or clear a fixed destination transport address for a datagram socket.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SIO_WSK_SET_TCP_SILENT_MODE control code

Article • 03/03/2023

The **SIO_WSK_SET_TCP_SILENT_MODE** socket I/O control operation allows a WSK client to enable silent mode on the TCP connection.

A TCP connection in silent mode will not send any data or control packets on the wire. This socket I/O control operation applies only to connected TCP sockets. It is not supported on loopback.

To perform this operation, call the WskControlSocket function with the following parameters.

Parameters

RequestType [in]
Use **WskIoctl** for this operation.

ControlCode [in]
The control code for the operation. Use **SIO_WSK_SET_TCP_SILENT_MODE** for this operation.

Level
Use zero for this operation.

InputSize [in]
Use zero for this operation.

InputBuffer [in]
Use **NULL** for this operation.

OutputSize [out]
Use zero for this operation.

OutputBuffer [in]
Use **NULL** for this operation.

OutputSizeReturned [out]
Use **NULL** for this operation.

Remarks

A WSK application must specify a pointer to an IRP when calling the WskControlSocket function to enable silent mode.

The WSK application before calling WskControlSocket to enable silent mode must ensure that there are no pending send or disconnect requests.

WskControlSocket will return **STATUS_SUCCESS** when silent mode is enabled. Once silent mode is enabled, send and disconnect requests will be failed with **STATUS_INVALID_DEVICE_STATE** and all received control or data packets will be discarded silently.

The only valid operation on this socket is WskCloseSocket.

Requirements

Version	Available in Windows 8, Windows Server 2012, and later.
Header	Wsk.h (include Wsk.h)

WskCloseSocket

WskControlSocket

SO_WSK_EVENT_CALLBACK

Article • 03/03/2023

The SO_WSK_EVENT_CALLBACK socket option allows a WSK application to enable and disable a socket's event callback functions. This socket option applies only to listening sockets, datagram sockets, connection-oriented sockets, and basic sockets that have registered an extension interface for which at least one event callback function is defined.

If a WSK application uses this socket option to enable or disable event callback functions on either a listening socket or a datagram socket, it must do so after the socket has been bound to a local transport address.

If a WSK application uses this socket option to enable or disable event callback functions on a connection-oriented socket, it must do so after the socket has been connected to a remote transport address.

To enable or disable event callback functions on a socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_WSK_EVENT_CALLBACK
Level	SOL_SOCKET
InputSize	sizeof(WSK_EVENT_CALLBACK_CONTROL)
InputBuffer	A pointer to a WSK_EVENT_CALLBACK_CONTROL structure
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

A WSK application does not specify a pointer to an IRP when calling the **WskControlSocket** function to enable event callback functions on a socket.

A WSK application can optionally specify a pointer to an IRP when calling the **WskControlSocket** function to disable an event callback function on a socket.

When a WSK application calls **WskControlSocket** to disable an event callback function, the WSK subsystem behaves as follows:

- If there are no in-progress calls to the event callback function that is being disabled when the WSK application calls the **WskControlSocket** function, the event callback function is disabled and the **WskControlSocket** function returns STATUS_SUCCESS. If the WSK application specifies an IRP, the IRP is completed with success status.

- If there are in-progress calls to the event callback function that is being disabled when the WSK application calls the **WskControlSocket** function and the WSK application specified an IRP, the **WskControlSocket** function returns STATUS_PENDING. The WSK subsystem disables the event callback function and completes the IRP after all in-progress calls to the event callback function have returned.

- If there are in-progress calls to the event callback function that is being disabled when the WSK application calls the **WskControlSocket** function and the WSK application did not specify an IRP, the **WskControlSocket** function returns STATUS_EVENT_PENDING. The WSK subsystem disables the event callback function after all in-progress calls to the event callback function have returned.

When enabling or disabling any of the standard WSK event callback functions, a WSK application sets the **NpiId** member of the **WSK_EVENT_CALLBACK_CONTROL** structure to a pointer to the WSK Network Programming Interface (NPI) identifier, NPI_WSK_INTERFACE_ID.

When enabling or disabling any callback functions for an extension interface, a WSK application sets the **NpiId** member of the WSK_EVENT_CALLBACK_CONTROL structure to a pointer to the NPI identifier for that extension interface.

When enabling event callback functions, a WSK application can simultaneously enable any combination of the event callback functions that are valid for a particular category of WSK socket. The WSK application simultaneously enables these combinations by setting the **EventMask** member of the WSK_EVENT_CALLBACK_CONTROL structure to a bitwise OR of the event flags for all of the event callback functions that are being enabled.

When disabling event callback functions, a WSK application must disable each event callback function independently. A WSK application independently disables an event callback function by setting the **EventMask** member of the WSK_EVENT_CALLBACK_CONTROL structure to a bitwise OR of the event flag for the event callback function that is being disabled and the WSK_EVENT_DISABLE flag.

The following table shows the valid event flags for a listening socket.

Event flag	Event callback function
WSK_EVENT_ACCEPT	*WskAcceptEvent*

The following table shows the valid event flags for a datagram socket.

Event flag	Event callback function
WSK_EVENT_RECEIVE_FROM	*WskReceiveFromEvent*

The following table shows the valid event flags for a connection-oriented socket.

Event flag	Event callback function
WSK_EVENT_DISCONNECT	*WskDisconnectEvent*
WSK_EVENT_RECEIVE	*WskReceiveEvent*
WSK_EVENT_SEND_BACKLOG	*WskSendBacklogEvent*

A listening socket can automatically enable event callback functions on connection-oriented sockets that are accepted by the listening socket. A WSK application automatically enables these callback functions by enabling the connection-oriented socket event callback functions on the listening socket. The event callback functions are automatically enabled on an accepted connection-oriented socket only if the socket is accepted by the listening socket's *WskAcceptEvent* event callback function. If the connection-oriented socket is accepted by the listening socket's **WskAccept** function, the accepted socket's event callback functions are not automatically enabled.

After any connection-oriented event callback functions are enabled on a listening socket, they cannot be disabled on the listening socket. If the *WskAcceptEvent* event callback function is disabled and then re-enabled on a listening socket, any connection-oriented event callback functions that were originally enabled on that listening socket will continue to be applied to all connection-oriented sockets that are accepted by the *WskAcceptEvent* event callback function.

For more information about enabling and disabling a socket's event callback functions, see Enabling and Disabling Event Callback Functions.

Requirements

Version	Available in Windows Vista and later versions of

	the Windows operating systems.
Header	Wsk.h (include Wsk.h)

SO_WSK_SECURITY

Article • 03/03/2023

The SO_WSK_SECURITY socket option allows a WSK application to either apply a security descriptor to a socket or retrieve a cached copy of a socket's security descriptor from a socket. The security descriptor controls the sharing of the local transport address to which the socket is bound.

This socket option applies only to listening sockets, datagram sockets, and connection-oriented sockets.

If a WSK application uses this socket option to apply a security descriptor to a socket, it must do so before the socket is bound to a local transport address.

To apply a security descriptor to a socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_WSK_SECURITY
Level	SOL_SOCKET
InputSize	sizeof(PSECURITY_DESCRIPTOR)
InputBuffer	A pointer to a PSECURITY_DESCRIPTOR-typed variable. This variable must contain a pointer to a cached copy of a security descriptor that was obtained by calling the WskControlClient function with the WSK_CACHE_SD control code.
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to apply a security descriptor to a socket.

If a WSK application uses this socket option to apply a security descriptor to a socket, the new security descriptor replaces any security descriptor that was previously applied to the socket.

A WSK application must not release the cached copy of the security descriptor until after the IRP is completed.

A WSK application can also apply a security descriptor to a socket when the socket is initially created by specifying a pointer to a cached copy of a security descriptor in the *SecurityDescriptor* parameter when it calls the WskSocket or WskSocketConnect function.

If a WSK application does not apply a security descriptor to a socket, the WSK subsystem uses a default security descriptor that does not allow sharing of the local transport address.

To retrieve a cached copy of a socket's security descriptor from a socket, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**
ControlCode	SO_WSK_SECURITY
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(PSECURITY_DESCRIPTOR)
OutputBuffer	A pointer to a PSECURITY_DESCRIPTOR-typed variable. This variable receives a pointer to a cached copy of the socket's security descriptor.
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to retrieve a cached copy of a socket's security descriptor from a socket.

A WSK application must call the WskControlClient function with the WSK_RELEASE_SD control code to release the cached copy of the security descriptor when it is no longer needed.

See the reference page for the SECURITY_DESCRIPTOR structure for more information.

Requirements

Version	Available in Windows Vista and later versions of

	the Windows operating systems.
Header	Wsk.h (include Wsk.h)

WSK_CLIENT

Article • 03/03/2023

The WSK_CLIENT data type defines the WSK subsystem's binding context for its attachment to a WSK application.

```c++
typedef PVOID PWSK_CLIENT;
```

PWSK_CLIENT
The contents of the **WSK_CLIENT** structure are opaque to a WSK application.

Remarks

When a WSK application calls the WskCaptureProviderNPI function, the WSK subsystem returns a pointer to a WSK_CLIENT structure to the WSK application by means of the *WskProviderNpi* parameter. The WSK subsystem uses this structure to track the state of the binding between the WSK application and the WSK subsystem. A WSK application passes this pointer as a parameter to all the functions in WSK_PROVIDER_DISPATCH (WskControlClient, WskSocket, and WskSocketConnect).

For more information, see Registering a Winsock Kernel Application.

Requirements

Version: Available in Windows Vista and later versions of the Windows operating systems.

Porting TDI Drivers to Winsock Kernel

Article • 12/15/2021

To port your TDI driver to Winsock Kernel (WSK), you'll need to convert TDI tasks to their WSK equivalents as shown in the following table.

Tasks	TDI	Winsock Kernel (WSK)
Register and Deregister	N/A	WskRegister and WskDeregister
Capture and Release Provider NPI	N/A	WskCaptureProviderNPI and WskReleaseProviderNPI
Create Address File Object	Create *EaBuffer*, then call ZwCreateFile	No longer necessary. See WskSocket.
Create Connection File Object	Create connection *EaBuffer*, then call ZwCreateFile	No longer necessary. See WskSocket and *WskAcceptEvent*.
Associate Address	TDI_ASSOCIATE_ADDRESS	WskBind
Set Event Handlers	TDI_SET_EVENT_HANDLER	WskControlSocket or static variation using WskControlClient
Clear Event Handlers	TDI_SET_EVENT_HANDLER	WskControlSocket
Connect	TDI_CONNECT	WskConnect
Disconnect	TDI_DISCONNECT	WskDisconnect
Send	TDI_SEND	WskSend
Receive	TDI_RECEIVE	WskReceive
Disassociate Address	TDI_DISASSOCIATE_ADDRESS	N/A
Receive Handler	ClientEventReceive, TDI_RECEIVE	*WskReceiveEvent*
Connect Handler	ClientEventConnect, TDI_CONNECT	WskAccept
Close Socket or Connection	ObDereferenceObject or ZwClose	WskCloseSocket

Sharing Transport Addresses

Article • 12/15/2021

In most situations, a Winsock Kernel (WSK) application cannot bind a socket to a local transport address that is already in use by another socket. WSK applications can use the SO_EXCLUSIVEADDRUSE and SO_REUSEADDR socket options to control the sharing of the local transport address to which a socket is bound. Neither of these socket options are set for a socket by default. For more information about setting socket options, see Performing Control Operations on a Socket.

The following table shows the result of binding a second socket to a local transport address that is already in use by another socket. The *Wildcard* and *Specific* cases specify whether the socket is bound to a wildcard local transport address or to a specific local transport address.

Second bind		**First bind**					
		No socket options (default)		SO_REUSEADDR		SO_EXCLUSIVEADDRUSE	
		Wildcard	Specific	Wildcard	Specific	Wildcard	Specific
No socket options (default)	Wildcard	INUSE	SUCCESS	INUSE	SUCCESS	INUSE	SUCCESS
	Specific	CHECK	INUSE	CHECK	DENIED	DENIED	INUSE
SO_REUSEADDR	Wildcard	DENIED	SUCCESS	SUCCESS	SUCCESS	DENIED	SUCCESS
	Specific	CHECK	DENIED	SUCCESS	SUCCESS	DENIED	DENIED
SO_EXCLUSIVEADDRUSE	Wildcard	INUSE	INUSE	INUSE	INUSE	INUSE	INUSE
	Specific	CHECK	INUSE	CHECK	INUSE	DENIED	INUSE

The results are defined as follows:

SUCCESS
The bind operation for the second socket succeeds. The WSK subsystem returns a status of STATUS_SUCCESS.

INUSE
The bind operation on the second socket fails. The WSK subsystem returns a status of STATUS_ADDRESS_ALREADY_EXISTS.

DENIED
The bind operation on the second socket fails. The WSK subsystem returns a status of STATUS_ACCESS_DENIED.

CHECK
An access check is performed to determine if the bind operation on the second socket succeeds or fails. If access is granted, the bind succeeds and the WSK subsystem returns a status of STATUS_SUCCESS. If access is denied, the bind fails and the WSK subsystem returns a status of STATUS_ACCESS_DENIED.

In the cases defined in the previous table where an access check is performed, the second socket's security context is checked against the first socket's security descriptor.

- A socket's security context is determined by the *OwningProcess* and *OwningThread* parameters that are passed to either the WskSocket function or the WskSocketConnect function when the socket is created. If no specific process or thread is specified when the socket is created, the security context of the process that created the socket is used.

- A socket's security descriptor is specified by the *SecurityDescriptor* parameter that is passed to either the WskSocket function or the WskSocketConnect function when the socket is created. If no specific security descriptor is specified, the WSK subsystem uses a default security descriptor that does not permit sharing of transport addresses. A security descriptor can also be applied to a socket after the socket has been created by using the SO_WSK_SECURITY socket option.

If the two sockets are bound to two different specific local transport addresses, there is no sharing of either transport address. In this situation the second bind operation will always complete successfully.

Using TDI Transports

Article • 12/15/2021

The Winsock Kernel (WSK) subsystem provides support for using TDI transports. In order to use TDI transports via the WSK Network Programming Interface (NPI), a WSK application must map the combination of address family, socket type, and protocol for each of the TDI transports it uses to the associated device name of each of those TDI transports. A WSK application maps combinations of address family, socket type, and protocol to device names of TDI transports by using the **WSK_TDI_DEVICENAME_MAPPING** client control operation.

The following code example shows how a WSK application can map combinations of address family, socket type, and protocol to device names of TDI transports.

C++

```cpp
// Number of TDI mappings
#define MAPCOUNT 2

// Array of TDI mappings
const WSK_TDI_MAP TdiMap[MAPCOUNT] =
{
  {SOCK_STREAM, ..., ..., ...},
  {SOCK_DGRAM, ..., ..., ...}
};

// TDI map info structure
const WSK_TDI_MAP_INFO TdiMapInfo =
{
  MAPCOUNT,
  TdiMap
}

// Function to set the TDI map
NTSTATUS
  SetTdiMap(
    PWSK_APP_BINDING_CONTEXT BindingContext
  )
{
  NTSTATUS Status;

  // Perform client control operation
  Status =
    BindingContext->
      WskProviderDispatch->
        WskControlClient(
          BindingContext->WskClient,
          WSK_TDI_DEVICENAME_MAPPING,
          sizeof(WSK_TDI_MAP_INFO),
          &TdiMapInfo,
          0,
          NULL,
          NULL,
          NULL  // No IRP for this control operation
          );

  // Return status of client control operation
  return Status;
}
```

A WSK application must map combinations of address family, socket type, and protocol to device names of TDI transports before it creates any sockets. After the WSK application has successfully mapped the combinations of address family, socket type, and protocol to device names of TDI transports, the application can then create new sockets that use the mapped TDI transports.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Using NMR for WSK Registration and Unregistration

Article • 12/15/2021

The Registering a Winsock Kernel Application and Unregistering a Winsock Kernel Application sections describe how a WSK application can attach to and detach from the WSK subsystem by using the WSK registration functions. However, WSK can also attach to the WSK subsystem by using the Network Module Registrar (NMR).

A WSK application can register itself with the NMR as a client of the WSK Network Programming Interface (NPI) by using the procedures in the following sections:

- Initializing NMR Data Structures
- Attaching the WSK Client to the WSK Subsystem
- Unregistering and Unloading the WSK Client

Using the **WskRegister** and **WskDeregister** functions is the preferred method for registering and unregistering WSK applications. The Network Module Registrar remains available for compatibility.

Initializing NMR Data Structures

Article • 12/15/2021

Before a Winsock Kernel (WSK) application can register with the Network Module Registrar (NMR), the application must first initialize the following structures.

- NPI_MODULEID
- NPI_CLIENT_CHARACTERISTICS
- NPI_REGISTRATION_INSTANCE contained within the NPI_CLIENT_CHARACTERISTICS structure

All of these data structures must remain valid and resident in memory as long as the WSK application is registered with the NMR.

The following code example shows how a WSK application can initialize all of the data structures listed previously.

C++

```
// Include the WSK header file
#include "wsk.h"

// Structure for the WSK application's network module identification
const NPI_MODULEID ModuleId =
{
  sizeof(NPI_MODULEID),
  MIT_GUID,
  { ... }  // A GUID that uniquely identifies the WSK application
};

// Prototypes for the WSK application's NMR API callback functions
NTSTATUS
  ClientAttachProvider(
    IN HANDLE NmrBindingHandle,
    IN PVOID ClientContext,
    IN PNPI_REGISTRATION_INSTANCE ProviderRegistrationInstance
    );

NTSTATUS
  ClientDetachProvider(
    IN PVOID ClientBindingContext
    );

VOID
  ClientCleanupBindingContext(
    IN PVOID ClientBindingContext
    );
```

```cpp
// Structure for the WSK application's characteristics
const NPI_CLIENT_CHARACTERISTICS Characteristics =
{
  0,
  sizeof(NPI_CLIENT_CHARACTERISTICS),
  ClientAttachProvider,
  ClientDetachProvider,
  ClientCleanupBindingContext,
  {
    0,
    sizeof(NPI_REGISTRATION_INSTANCE),
    &NPI_WSK_INTERFACE_ID,
    &ModuleId,
    0,
    NULL
  }
};
```

A WSK application calls the **NmrRegisterClient** function to register the application with the NMR.

For example:

C++

```cpp
// Variable to contain the handle for the registration with the NMR
HANDLE RegistrationHandle;

// DriverEntry function
NTSTATUS
  DriverEntry(
    PDRIVER_OBJECT DriverObject,
    PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS Status;

  .
  .
  .

  // Register the WSK application with the NMR
  Status = NmrRegisterClient(
    &Characteristics,
    NULL,
    &RegistrationHandle
    );

  if(!NT_SUCCESS(Status)) {
      .
      .
      .
      return Status;
  }

  .
  .
  .
}
```

A WSK application is not required to call **NmrRegisterClient** from within its **DriverEntry** function. For example, if a WSK application is a subcomponent of a complex driver, the registration of the application might occur only when the WSK application subcomponent is activated.

Attaching the WSK Client to the WSK Subsystem

Article • 12/15/2021

After a Winsock Kernel (WSK) application has registered with the Network Module Registrar (NMR) as a client of the WSK NPI, the NMR immediately calls the application's *ClientAttachProvider* callback function if the WSK subsystem is loaded and has registered itself with the NMR. If the WSK subsystem is not registered with the NMR, the NMR does not call the application's *ClientAttachProvider* callback function until the WSK subsystem registers with the NMR.

The WSK application should make the following sequence of calls to complete the attachment procedure.

1. When the NMR calls the WSK application's *ClientAttachProvider* callback function, it passes a pointer to the **NPI_REGISTRATION_INSTANCE** structure associated with the WSK subsystem. The WSK application's *ClientAttachProvider* callback function can use the data passed to it by the NMR to determine if it can attach to the WSK subsystem. Typically, a WSK application only needs the version information contained within a **WSK_PROVIDER_CHARACTERISTICS** structure that is pointed to by the **NpiSpecificCharacteristics** member of the WSK subsystem's NPI_REGISTRATION_INSTANCE structure.

2. If the WSK application determines that it can attach to the WSK subsystem, the WSK application's *ClientAttachProvider* callback function allocates and initializes a binding context structure for the attachment to the WSK subsystem. The application then calls the **NmrClientAttachProvider** function to continue the attachment process.

   If **NmrClientAttachProvider** returns STATUS_SUCCESS, the WSK application has successfully attached to the WSK subsystem. In this situation, the WSK application's *ClientAttachProvider* callback function must save the binding handle that the NMR passed in the *NmrBindingHandle* parameter when the NMR called the application's *ClientAttachProvider* callback function. The WSK application's *ClientAttachProvider* callback function must also save the pointers to the client object (**WSK_CLIENT**) and the provider dispatch table (**WSK_PROVIDER_DISPATCH**) that are returned in the variables that the application passed to the **NmrClientAttachProvider** function in the *ProviderBindingContext* and *ProviderDispatch* parameters. A WSK application typically saves this data in its binding context for the attachment to the WSK subsystem. After the WSK application has successfully attached to the WSK subsystem, the WSK application's *ClientAttachProvider* callback function must return STATUS_SUCCESS.

3. If **NmrClientAttachProvider** returns STATUS_NOINTERFACE, the WSK application can make another attempt to attach to the WSK subsystem by calling the **NmrClientAttachProvider** function again, passing a *ClientDispatch* pointer to a different WSK_CLIENT_DISPATCH structure that specifies an alternate version of the WSK NPI that is supported by the application.

4. If a call to the **NmrClientAttachProvider** function does not return STATUS_SUCCESS, and the WSK application does not make any further attempts to attach to the WSK subsystem, the WSK application's *ClientAttachProvider* callback function should clean up and deallocate any resources that it allocated before it called **NmrClientAttachProvider**. In this situation, the WSK application's *ClientAttachProvider* callback function must return the status code that was returned by the last call to the **NmrClientAttachProvider** function.

5. If the WSK application determines that it cannot attach to the provider module, the application's *ClientAttachProvider* callback function must return STATUS_NOINTERFACE.

The following code example shows how a WSK application can attach itself to the WSK subsystem.

C++

```
// Context structure type for the WSK application's
// binding to the WSK subsystem
typedef struct WSK_APP_BINDING_CONTEXT_ {
  HANDLE NmrBindingHandle;
  PWSK_CLIENT WskClient;
  PWSK_PROVIDER_DISPATCH WskProviderDispatch;
  .
  . // Other application-specific members
  .
} WSK_APP_BINDING_CONTEXT, *PWSK_APP_BINDING_CONTEXT;

// Pool tag used for allocating the binding context
#define BINDING_CONTEXT_POOL_TAG 'tpcb'

// The WSK application uses version 1.0 of WSK
#define WSK_APP_WSK_VERSION MAKE_WSK_VERSION(1,0)

// Structure for the WSK application's dispatch table
const WSK_CLIENT_DISPATCH WskAppDispatch = {
  WSK_APP_WSK_VERSION,
  0,
  NULL  // No WskClientEvent callback
```

```
};

// ClientAttachProvider NMR API callback function
NTSTATUS
  ClientAttachProvider(
    IN HANDLE NmrBindingHandle,
    IN PVOID ClientContext,
    IN PNPI_REGISTRATION_INSTANCE ProviderRegistrationInstance
    )
{
  PNPI_MODULEID WskProviderModuleId;
  PWSK_PROVIDER_CHARACTERISTICS WskProviderCharacteristics;
  PWSK_APP_BINDING_CONTEXT BindingContext;
  PWSK_CLIENT WskClient;
  PWSK_PROVIDER_DISPATCH WskProviderDispatch;
  NTSTATUS Status;

  // Get pointers to the WSK subsystem's identification and
  // characteristics structures
  WskProviderModuleId = ProviderRegistrationInstance->ModuleId;
  WskProviderCharacteristics =
    (PWSK_PROVIDER_CHARACTERISTICS)
      ProviderRegistrationInstance->NpiSpecificCharacteristics;

  //
  // The WSK application can use the data in the structures pointed
  // to by ProviderRegistrationInstance, WskProviderModuleId, and
  // WskProviderCharacteristics to determine if the WSK application
  // can attach to the WSK subsystem.
  //
  // In this example, the WSK application does not perform any
  // checks to determine if it can attach to the WSK subsystem.
  //

  // Allocate memory for the WSK application's binding
  // context structure
  BindingContext =
    (PWSK_APP_BINDING_CONTEXT)
      ExAllocatePoolWithTag(
        NonPagedPool,
        sizeof(WSK_APP_BINDING_CONTEXT),
        BINDING_CONTEXT_POOL_TAG
        );

  // Check result of allocation
  if (BindingContext == NULL)
  {
    // Return error status code
    return STATUS_INSUFFICIENT_RESOURCES;
  }

  // Initialize the binding context structure
  ...

  // Continue with the attachment to the WSK subsystem
  Status = NmrClientAttachProvider(
    NmrBindingHandle,
    BindingContext,
    &WskAppDispatch,
    &WskClient,
    &WskProviderDispatch
    );

  // Check result of attachment
  if (Status == STATUS_SUCCESS)
  {
    // Save NmrBindingHandle, WskClient, and
    // WskProviderDispatch for future reference
    BindingContext->NmrBindingHandle = NmrBindingHandle;
    BindingContext->WskClient = WskClient;
    BindingContext->WskProviderDispatch = WskProviderDispatch;
  }

  // Attachment did not succeed
  else
  {
    // Free memory for application's binding context structure
    ExFreePoolWithTag(
      BindingContext,
      BINDING_CONTEXT_POOL_TAG
      );
  }

  // Return result of attachment
  return Status;
}
```

Unregistering and Unloading the WSK Client

Article • 12/15/2021

Any Winsock Kernel (WSK) application that uses the Network Module Registrar (NMR) for attaching to the WSK subsystem must unregister with NMR before unloading. When a WSK application unregisters with the NMR by calling the **NmrDeregisterClient** function, the NMR calls the application's *ClientDetachProvider* callback function so that the application can detach itself from the WSK subsystem as part of the WSK application's unregistration process.

Furthermore, in the unlikely, but possible, case of the WSK subsystem unregistering with the NMR, the NMR also calls the WSK application's *ClientDetachProvider* callback function so that the application can detach itself from the WSK subsystem as part of the WSK subsystem's unregistration process.

The NMR calls a WSK application's *ClientDetachProvider* callback function only once. If both the WSK application and the WSK subsystem unregister with the NMR, the NMR calls the WSK application's *ClientDetachProvider* callback function only after the first unregistration is initiated.

If there are no calls in progress to any of the WSK functions in WSK_PROVIDER_DISPATCH at the time that the NMR calls the WSK application's *ClientDetachProvider* callback function, the WSK application should return STATUS_SUCCESS from its *ClientDetachProvider* callback function. Otherwise, the WSK application must return STATUS_PENDING from its *ClientDetachProvider* callback function, and it must call the **NmrClientDetachProviderComplete** function after all of the calls in progress to the WSK functions in WSK_PROVIDER_DISPATCH have returned. A WSK application calls the **NmrClientDetachProviderComplete** function to notify the NMR that the application has detached from the WSK subsystem. However, the WSK subsystem will not allow the detachment procedure to be completed fully until all open sockets are closed by the WSK application. For more information, see Closing a Socket.

After a WSK application has notified the NMR that detachment is complete, either by returning STATUS_SUCCESS from its *ClientDetachProvider* callback function or by calling the **NmrClientDetachProviderComplete** function, the application must not make any further calls to any of the WSK functions in WSK_PROVIDER_DISPATCH.

If a WSK application implements a *ClientCleanupBindingContext* callback function, the NMR calls the application's *ClientCleanupBindingContext* callback function after both the WSK application and the WSK subsystem have completed detachment from each other.

A WSK application's *ClientCleanupBindingContext* callback function should perform any necessary cleanup of the data contained within the application's binding context structure. It should then free the memory for the binding context structure if the application dynamically allocated memory for the structure.

For example:

```C++
// ClientDetachProvider callback function
NTSTATUS
  ClientDetachProvider(
    IN PVOID ClientBindingContext
    )
{
  PWSK_APP_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext =
    (PWSK_APP_BINDING_CONTEXT)ClientBindingContext;

  // Check if there are no calls in progress to any WSK functions
  // in WSK_PROVIDER_DISPATCH and that there are no open sockets
  if (...)
  {
    // Return success status indicating that detachment is complete
    return STATUS_SUCCESS;
  }

  // There are calls in progress to one or more of the WSK functions
  // in WSK_PROVIDER_DISPATCH and/or one or more open sockets
  else
  {
    // Return pending status, indicating that detachment is pending
    // completion of the calls in progress to the WSK functions in
    // WSK_PROVIDER_DISPATCH and/or closing of the open sockets
    return STATUS_PENDING;

    // When all of the calls in progress to the WSK functions
    // in WSK_PROVIDER_DISPATCH are completed, the WSK application
    // must close all open sockets.
    //
    // After all sockets have been closed, the WSK application must
    // call the NmrClientDetachProviderComplete function with the
    // binding handle for the attachment to the WSK subsystem.
  }
}

// ClientCleanupBindingContext callback function
VOID
  ClientCleanupBindingContext(
    IN PVOID ClientBindingContext
    )
```

```
{
  PWSK_APP_BINDING_CONTEXT BindingContext;

  // Get a pointer to the binding context
  BindingContext =
    (PWSK_APP_BINDING_CONTEXT)ClientBindingContext;

  // Clean up the binding context structure
  ...

  // Free the memory for client's binding context structure
  ExFreePoolWithTag(
    BindingContext,
    BINDING_CONTEXT_POOL_TAG
    );
}
```

A WSK application's **Unload** function must ensure that the application is unregistered from the NMR before the application is unloaded from system memory. A WSK application must not return from its *Unload* function until after it has been completely unregistered from the NMR. If the call to **NmrDeregisterClient** returns STATUS_PENDING, the WSK application must call the **NmrWaitForClientDeregisterComplete** function to wait for the unregistration to complete before it returns from its *Unload* function.

For example:

C++

```
// Variable containing the handle for registration with the NMR
HANDLE RegistrationHandle;

// Unload function
VOID
  Unload(
    IN PDRIVER_OBJECT DriverObject
    )
{
  NTSTATUS Status;

  // Unregister the WSK application from the NMR
  Status =
    NmrDeregisterClient(
      RegistrationHandle
      );

  // Check if pending
  if (Status == STATUS_PENDING)
  {
    // Wait for the unregistration to be completed
    NmrWaitForClientDeregisterComplete(
      RegistrationHandle
      );
  }
}
```

A WSK application is not required to call **NmrDeregisterClient** from within its *Unload* function. For example, if a WSK application is a subcomponent of a complex driver, the unregistration of the WSK application might occur when the WSK application subcomponent is deactivated. However, in such a situation the driver must still ensure that the WSK application has been completely unregistered from the NMR before returning from its *Unload* function.

IP Helper Overview

Article • 06/30/2022

Internet Protocol Helper (IP Helper) enables drivers to retrieve information about the network configuration of the local computer and to modify that configuration. IP Helper also provides notification mechanisms to make sure that a driver is notified when certain aspects of the local computer network configuration change. IP Helper is available in Windows Vista and later versions of the Microsoft Windows operating systems.

Many of the IP Helper functions pass structure parameters that represent data types that are associated with the Management Information Base (MIB) technology. The IP Helper functions use these MIB structures to represent various networking information.

The IP Helper documentation uses the terms "adapter" and "interface" extensively. An *adapter* is a legacy term that is an abbreviated form of *network adapter*, which originally referred to some form of network hardware. An adapter is a data link-level abstraction.

An *interface* is described in the IETF RFC documents as an abstract concept that represents a node's attachment to a link. An interface is an IP-level abstraction.

Your driver can use the following kernel-mode functions, MIB structures, and MIB and Network Layer (NL) enumerations to retrieve and modify configuration settings for Transmission Control Protocol/Internet Protocol (TCP/IP) transport on a local computer.

> ⓘ Note
>
> When you are developing driver code, follow the instructions for **including header files.**

Interface Conversion Functions

Function	Description
ConvertInterfaceAliasToLuid	Converts a locally unique identifier (LUID) for a network interface to the Unicode interface name.
ConvertInterfaceGuidToLuid	Converts a globally unique identifier (GUID) for a network interface to the LUID for the interface.

Function	Description
ConvertInterfaceIndexToLuid	Converts a local index for a network interface to the LUID for the interface.
ConvertInterfaceLuidToAlias	Converts a LUID for a network interface to an interface alias.
ConvertInterfaceLuidToGuid	Converts a LUID for a network interface to a GUID for the interface.
ConvertInterfaceLuidToIndex	Converts a LUID for a network interface to the local index for the interface.
ConvertInterfaceLuidToNameA	Converts a LUID for a network interface to the ANSI interface name.
ConvertInterfaceLuidToNameW	Converts a LUID for a network interface to the Unicode interface name.
ConvertInterfaceNameToLuidA	Converts an ANSI network interface name to the LUID for the interface.
ConvertInterfaceNameToLuidW	Converts a Unicode network interface name to the LUID for the interface.
if_indextoname	Converts the local index for a network interface to the ANSI interface name.
if_nametoindex	Converts the ANSI interface name for a network interface to the local index for the interface.

Interface Management Functions

Function	Description
GetIfEntry2	Retrieves information for the specified interface on the local computer.
GetIfStackTable	Retrieves a table of network interface stack row entries that specify the relationship of the network interfaces on an interface stack.
GetIfTable2	Retrieves the MIB-II interface table.
GetIfTable2Ex	Retrieves the MIB-II interface table, given a level of interface information to retrieve.

Function	Description
GetInvertedIfStackTable	Retrieves a table of inverted network interface stack row entries that specify the relationship of the network interfaces on an interface stack.
GetIpInterfaceEntry	Retrieves IP information for the specified interface on the local computer.
GetIpInterfaceTable	Retrieves the IP interface entries on the local computer.
InitializeIpInterfaceEntry	Initializes the members of a MIB_IPINTERFACE_ROW structure entry with default values.
SetIpInterfaceEntry	Sets the properties of an IP interface on the local computer.

IP Address Management Functions

Function	Description
CreateAnycastIpAddressEntry	Adds a new anycast IP address entry on the local computer.
CreateSortedAddressPairs	Pairs a supplied list of destination addresses together with the host machine's local IP addresses and sorts the pairs according to the preferred order of communication.
CreateUnicastIpAddressEntry	Adds a new unicast IP address entry on the local computer.
DeleteAnycastIpAddressEntry	Deletes an existing anycast IP address entry on the local computer.
DeleteUnicastIpAddressEntry	Deletes an existing unicast IP address entry from the local computer.
GetAnycastIpAddressEntry	Retrieves information for an existing anycast IP address entry on the local computer.
GetAnycastIpAddressTable	Retrieves the anycast IP address table on the local computer.
GetMulticastIpAddressEntry	Retrieves information for an existing multicast IP address entry on the local computer.

Function	Description
GetMulticastIpAddressTable	Retrieves the multicast IP address table on the local computer.
GetUnicastIpAddressEntry	Retrieves information for an existing unicast IP address entry on the local computer.
GetUnicastIpAddressTable	Retrieves the unicast IP address table on the local computer.
InitializeUnicastIpAddressEntry	Initializes a MIB_UNICASTIPADDRESS_ROW structure with default values for a unicast IP address entry on the local computer.
NotifyStableUnicastIpAddressTable	Retrieves the stable unicast IP address table on a local computer.
SetUnicastIpAddressEntry	Sets the properties of an existing unicast IP address entry on the local computer.

IP Neighbor Address Management Functions

Function	Description
CreateIpNetEntry2	Creates a new neighbor IP address entry on the local computer.
DeleteIpNetEntry2	Deletes a neighbor IP address entry from the local computer.
FlushIpNetTable2	Flushes the IP neighbor table on the local computer.
GetIpNetEntry2	Retrieves information for a neighbor IP address entry on the local computer.
GetIpNetTable2	Retrieves the IP neighbor table on the local computer.
ResolveIpNetEntry2	Resolves the physical address for a neighbor IP address entry on the local computer.
SetIpNetEntry2	Sets the physical address of an existing neighbor IP address entry on the local computer.

IP Path Management Functions

Function	Description
FlushIpPathTable	Flushes the IP path table on the local computer.
GetIpPathEntry	Retrieves information for an IP path entry on the local computer.
GetIpPathTable	Retrieves information for an IP path entry on the local computer.

IP Route Management Functions

Function	Description
CreateIpForwardEntry2	Creates a new IP route entry on the local computer.
DeleteIpForwardEntry2	Deletes an IP route entry from the local computer.
GetBestRoute2	Retrieves the IP route entry on the local computer for the best route to the specified destination IP address.
GetIpForwardEntry2	Retrieves information for an IP route entry on the local computer.
GetIpForwardTable2	Retrieves the IP route entries on the local computer.
InitializeIpForwardEntry	Initializes a MIB_IPFORWARD_ROW2 structure with default values for an IP route entry on the local computer.
SetIpForwardEntry2	Sets the properties of an IP route entry on the local computer.

IP Table Memory Management Functions

Function	Description
FreeMibTable	Frees the buffer that is allocated by the functions that return tables of network interfaces, addresses, and routes (for example, GetIfTable2 and GetAnycastIpAddressTable).

Notification Functions

Function	Description
CancelMibChangeNotify2	Deregisters the driver for change notifications for IP interface changes, IP address changes, IP route changes, and requests to retrieve the stable unicast IP address table.
NotifyIpInterfaceChange	Registers the driver to be notified for changes to all IP interfaces, IPv4 interfaces, or IPv6 interfaces on a local computer.
NotifyRouteChange2	Registers to be notified for changes to IP route entries on a local computer.
NotifyUnicastIpAddressChange	Registers to be notified for changes to all unicast IP interfaces, unicast IPv4 addresses, or unicast IPv6 addresses on a local computer.

Teredo IPv6 Client Management Functions

Function	Description
GetTeredoPort	Retrieves the dynamic UDP port number that the Teredo client uses on the local computer.
NotifyTeredoPortChange	Registers to be notified for changes to the UDP port number that the Teredo client uses for the Teredo service port on a local computer.
NotifyStableUnicastIpAddressTable	Retrieves the stable unicast IP address table on a local computer.

MIB Structures

Structure	Description
IP_ADDRESS_PREFIX	Stores an IP address prefix.
MIB_ANYCASTIPADDRESS_ROW	Stores information about an anycast IP address.
MIB_ANYCASTIPADDRESS_TABLE	Contains a table of anycast IP address entries.
MIB_IF_ROW2	Stores information about a particular interface.
MIB_IF_TABLE2	Contains a table of logical and physical interface entries.

Structure	Description
MIB_IFSTACK_ROW	Represents the relationship between two network interfaces.
MIB_IFSTACK_TABLE	Contains a table of row entries in the network interface stack. This table specifies the relationship of the network interfaces on an interface stack.
MIB_INVERTEDIFSTACK_ROW	Represents the relationship between two network interfaces.
MIB_INVERTEDIFSTACK_TABLE	Contains a table of inverted network interface stack row entries. This table specifies the relationship of the network interfaces on an interface stack in reverse order.
MIB_IPFORWARD_ROW2	Stores information about an IP route entry.
MIB_IPFORWARD_TABLE2	Contains a table of IP route entries.
MIB_IPINTERFACE_ROW	Stores interface management information for a particular IP address family on a network interface.
MIB_IPINTERFACE_TABLE	Contains a table of IP interface entries.
MIB_IPNET_ROW2	Stores information about a neighbor IP address.
MIB_IPNET_TABLE2	Contains a table of neighbor IP address entries.
MIB_IPPATH_ROW	Stores information about an IP path entry.
MIB_IPPATH_TABLE	Contains a table of IP path entries.
MIB_MULTICASTIPADDRESS_ROW	Stores information about a multicast IP address.
MIB_MULTICASTIPADDRESS_TABLE	Contains a table of multicast IP address entries.
MIB_UNICASTIPADDRESS_ROW	Stores information about a unicast IP address.
MIB_UNICASTIPADDRESS_TABLE	Contains a table of unicast IP address entries.

MIB Enumerations

Enumeration	Description
MIB_IF_TABLE_LEVEL	Defines the level of interface information to retrieve.

Enumeration	Description
MIB_NOTIFICATION_TYPE	Defines the notification type that is passed to a callback function when a notification occurs.

NL Enumerations

Enumeration	Description
NL_ADDRESS_TYPE	Specifies the IP address type of the network layer.
NL_DAD_STATE	Defines the duplicate address detection (DAD) state.
NL_LINK_LOCAL_ADDRESS_BEHAVIOR	Defines the link local address behavior.
NL_NEIGHBOR_STATE	Defines the state of a network layer neighbor IP address, as described in RFC 2461, section 7.3.2.
NL_PREFIX_ORIGIN	Defines the origin of the prefix or network part of the IP address.
NL_ROUTE_ORIGIN	Defines the origin of the IP route.
NL_ROUTE_PROTOCOL	Defines the routing mechanism that an IP route was added with, as described in RFC 4292.
NL_ROUTER_DISCOVERY_BEHAVIOR	Defines the router discovery behavior, as described in RFC 2461.
NL_SUFFIX_ORIGIN	Defines the origin of the suffix or host part of the IP address.

Including Header Files for IP Helper

Article • 06/30/2022

Driver code that uses the kernel-mode IP Helper functions, MIB structures, and enumerations that are declared in Netioapi.h must have **#include** statements in the following sequence.

```C++
#include <ntddk.h>
#include <netioapi.h>
```

Note Do not include Iphlpapi.h in driver code. It is used only for user-mode applications.

When Netioapi.h is used with kernel-mode drivers, it already includes networking header files that define Winsock Kernel, network interface information, the network layer, and Network Driver Interface Specification (NDIS) types.

Therefore, do not include the following header files in your driver code:

- Ifdef.h
- Nldef.h
- Ws2def.h
- Ws2ipdef.h

For information about the user-mode versions of the IP Helper functions and MIB structures, see the Windows SDK IP Helper documentation.

ConvertInterfaceAliasToLuid function

Article • 03/03/2023

The **ConvertInterfaceAliasToLuid** function converts an interface alias name for a network interface to the locally unique identifier (LUID) for the interface.

> ⓘ Note
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

C++

```
NETIOAPI_API ConvertInterfaceAliasToLuid(
  _In_  const WCHAR     *InterfaceAlias,
  _Out_       PNET_LUID InterfaceLuid
);
```

Parameters

- *InterfaceAlias* [in]
  A pointer to a NULL-terminated Unicode string that contains the alias name of the network interface.

- *InterfaceLuid* [out]
  A pointer to the NET_LUID union for the network interface.

Return value

ConvertInterfaceAliasToLuid returns STATUS_SUCCESS if the function succeeds. If the function fails, the *InterfaceLuid* parameter is set to **NULL**, and **ConvertInterfaceAliasToLuid** returns the following error code:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters was invalid. **ConvertInterfaceAliasToLuid** returns this error if either *InterfaceAlias* or *InterfaceLuid* is **NULL**, or if *InterfaceAlias* is invalid.

Remarks

The **ConvertInterfaceAliasToLuid** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	PASSIVE_LEVEL

NET_LUID

ConvertInterfaceGuidToLuid function

Article • 03/03/2023

The **ConvertInterfaceGuidToLuid** function converts a globally unique identifier (GUID) for a network interface to the locally unique identifier (LUID) for the interface.

> ⓘ Note
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```C++
NETIOAPI_API ConvertInterfaceGuidToLuid(
  _In_  const GUID      *InterfaceGuid,
  _Out_       PNET_LUID InterfaceLuid
);
```

Parameters

- *InterfaceGuid* [in]

  A pointer to a GUID for the network interface.

- *InterfaceLuid* [out]

  A pointer to the **NET_LUID** union for the network interface.

Return value

ConvertInterfaceGuidToLuid returns STATUS_SUCCESS if the function succeeds. If the function fails, the *InterfaceLuid* parameter is set to **NULL**, and **ConvertInterfaceGuidToLuid** returns the following error code:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters was invalid. **ConvertInterfaceGuidToLuid** returns this error if either *InterfaceAlias* or *InterfaceLuid* is **NULL**, or if *InterfaceGuid* is invalid.

Remarks

The **ConvertInterfaceGuidToLuid** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	PASSIVE_LEVEL

NET_LUID

ConvertInterfaceIndexToLuid function

Article • 03/03/2023

The **ConvertInterfaceIndexToLuid** function converts a local index for a network interface to the locally unique identifier (LUID) for the interface.

> ⓘ Note
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```c++
NETIOAPI_API ConvertInterfaceIndexToLuid(
  _In_  NET_IFINDEX InterfaceIndex,
  _Out_ PNET_LUID   InterfaceLuid
);
```

Parameters

- *InterfaceIndex* [in]
  The local index value for the network interface.

- *InterfaceLuid* [out]
  A pointer to the NET_LUID union for the network interface.

Return value

ConvertInterfaceIndexToLuid returns STATUS_SUCCESS if the function succeeds. If the function fails, the *InterfaceLuid* parameter is set to **NULL**, and **ConvertInterfaceIndexToLuid** returns the following error code:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters was invalid. **ConvertInterfaceIndexToLuid** returns this error if the *InterfaceLuid* parameter is **NULL**, or if the *InterfaceIndex* parameter is invalid.

Remarks

The **ConvertInterfaceIndexToLuid** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	PASSIVE_LEVEL

NET_LUID

ConvertInterfaceLuidToAlias function

Article • 03/03/2023

The **ConvertInterfaceLuidToAlias** function converts a locally unique identifier (LUID) for a network interface to an interface alias.

> **Note**
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```c++
NETIOAPI_API ConvertInterfaceLuidToAlias(
  _In_  const NET_LUID *InterfaceLuid,
  _Out_       PWSTR    InterfaceAlias,
  _In_        SIZE_T   Length
);
```

Parameters

- *InterfaceLuid* [in]
  A pointer to a **NET_LUID** union for the network interface.

- *InterfaceAlias* [out]
  A pointer to a buffer to hold the NULL-terminated Unicode string. If **ConvertInterfaceLuidToAlias** returns successfully, *InterfaceAlias* contains the alias name of the network interface.

- *Length* [in]
  The length, by character count, of the buffer that the *InterfaceAlias* parameter points to. This value must be large enough to hold the alias name of the network interface and the terminating NULL character. The maximum allowed length is NDIS_IF_MAX_STRING_SIZE + 1. For more information about NDIS_IF_MAX_STRING_SIZE, see the following Remarks section.

Return value

ConvertInterfaceLuidToAlias returns STATUS_SUCCESS if the function succeeds. If the function fails, **ConvertInterfaceLuidToAlias** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceLuidToAlias** returns this error if either *InterfaceLuid* or *InterfaceAlias* is **NULL**, or if *InterfaceLuid* is invalid.
STATUS_NOT_ENOUGH_MEMORY	Not enough storage is available. **ConvertInterfaceLuidToAlias** returns this error if the size of the buffer that the *InterfaceAlias* parameter points to was not as large as specified in the *Length* parameter and, therefore, the buffer could not hold the alias name.

Remarks

The **ConvertInterfaceLuidToAlias** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

The maximum length of the alias name for a network interface, NDIS_IF_MAX_STRING_SIZE, without the terminating NULL character, is declared in the *Ntddndis.h* header file. NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant, which is defined in the *Ifdef.h* header file.

> ⓘ **Note**
>
> The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

Library	Netio.lib
IRQL	PASSIVE_LEVEL

ConvertInterfaceLuidToGuid function

Article • 03/03/2023

The **ConvertInterfaceLuidToGuid** function converts a locally unique identifier (LUID) for a network interface to a globally unique identifier (GUID) for the interface.

> Note
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```c++
NETIOAPI_API ConvertInterfaceLuidToGuid(
  _In_  const NET_LUID *InterfaceLuid,
  _Out_       GUID     *InterfaceGuid
);
```

Parameters

- *InterfaceLuid* [in]

  A pointer to a **NET_LUID** union for the network interface.

- *InterfaceGuid* [out]

  A pointer to the GUID for the network interface.

Return value

ConvertInterfaceLuidToGuid returns STATUS_SUCCESS if the function succeeds. If the function fails, the *InterfaceGuid* parameter is set to **NULL**, and **ConvertInterfaceLuidToGuid** returns the following error code:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceLuidToGuid** returns this error if either *InterfaceLuid* or *InterfaceGuid* is **NULL**, or if *InterfaceLuid* is invalid.

Remarks

The **ConvertInterfaceLuidToGuid** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

NET_LUID

ConvertInterfaceLuidToIndex function

Article • 03/03/2023

The **ConvertInterfaceLuidToIndex** function converts a locally unique identifier (LUID) for a network interface to the local index for the interface.

> ⓘ Note
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

C++

```
NETIOAPI_API ConvertInterfaceLuidToIndex(
  _In_  const NET_LUID     *InterfaceLuid,
  _Out_       PNET_IFINDEX InterfaceIndex
);
```

Parameters

- *InterfaceLuid* [in]
  A pointer to a **NET_LUID** union for the network interface.

- *InterfaceIndex* [out]
  The local index value for the network interface.

Return value

ConvertInterfaceLuidToIndex returns STATUS_SUCCESS if the function succeeds. If the function fails, the *InterfaceIndex* parameter is set to NET_IFINDEX_UNSPECIFIED, and **ConvertInterfaceLuidToIndex** returns the following error code:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceLuidToIndex** returns this error if either *InterfaceLuid* or *InterfaceIndex* is **NULL**, or if *InterfaceLuid* is invalid.

Remarks

The **ConvertInterfaceLuidToIndex** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

NET_LUID

ConvertInterfaceLuidToNameA function

Article • 03/03/2023

The **ConvertInterfaceLuidToNameA** function converts a locally unique identifier (LUID) for a network interface to the ANSI interface name.

> **Note**
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

C++

```
NETIOAPI_API ConvertInterfaceLuidToNameA(
  _In_  const NET_LUID *InterfaceLuid,
  _Out_       PSTR     InterfaceName,
  _In_        SIZE_T   Length
);
```

Parameters

- *InterfaceLuid* [in]
  A pointer to a NET_LUID union for a network interface.

- *InterfaceName* [out]
  A pointer to a buffer to hold the NULL-terminated ANSI string. If **ConvertInterfaceLuidToNameA** returns successfully, *InterfaceName* contains the ANSI interface name.

- *Length* [in]
  The length, in bytes, of the buffer that the *InterfaceName* parameter points to. This value must be large enough to hold the interface name and the terminating NULL character. The maximum allowed length is NDIS_IF_MAX_STRING_SIZE + 1. For more information about NDIS_IF_MAX_STRING_SIZE, see the following Remarks section.

Return value

ConvertInterfaceLuidToNameA returns STATUS_SUCCESS if the function succeeds. If the function fails, **ConvertInterfaceLuidToNameA** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceLuidToNameA** returns this error if either *InterfaceLuid* or *InterfaceName* is **NULL**, or if *InterfaceLuid* is invalid.
STATUS_NOT_ENOUGH_MEMORY	**ConvertInterfaceLuidToNameA** returns this error if the *InterfaceName* buffer was not as large as specified in the *Length* parameter and, therefore, the buffer could not hold the interface name.

Remarks

The **ConvertInterfaceLuidToNameA** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

The maximum length of the name for a network interface, NDIS_IF_MAX_STRING_SIZE, without the terminating NULL character, is defined in the Ntddndis.h header file. NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant, which is defined in the Ifdef.h header file.

ⓘ Note

The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

Use the ConvertInterfaceLuidToNameW function to convert a network interface LUID to a Unicode interface name.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

ConvertInterfaceLuidToNameW function

Article • 03/03/2023

The **ConvertInterfaceLuidToNameW** function converts a locally unique identifier (LUID) for a network interface to the Unicode interface name.

> **Note**
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```c++
NETIOAPI_API ConvertInterfaceLuidToNameW(
  _In_  const NET_LUID *InterfaceLuid,
  _Out_       PWSTR    InterfaceName,
  _In_        SIZE_T   Length
);
```

Parameters

- *InterfaceLuid* [in]
  A pointer to a **NET_LUID** union for the network interface.

- *InterfaceName* [out]
  A pointer to a buffer to hold the NULL-terminated Unicode string. If **ConvertInterfaceLuidToNameW** returns successfully, *InterfaceName* contains the Unicode interface name.

- *Length* [in]
  The length of the buffer, by character count, that the *InterfaceName* parameter points to. This value must be large enough to hold the interface name and the terminating NULL character. The maximum allowed length is NDIS_IF_MAX_STRING_SIZE + 1. For more information about NDIS_IF_MAX_STRING_SIZE, see the following Remarks section.

Return value

ConvertInterfaceLuidToNameW returns STATUS_SUCCESS if the function succeeds. If the function fails, **ConvertInterfaceLuidToNameW** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceLuidToNameW** returns this error if either *InterfaceLuid* or *InterfaceName* is **NULL**, or if *InterfaceLuid* is invalid.
STATUS_NOT_ENOUGH_MEMORY	**ConvertInterfaceLuidToNameW** returns this error if the *InterfaceName* buffer was not as large as specified in the *Length* parameter and, therefore, the buffer could not hold the interface name.

Remarks

The **ConvertInterfaceLuidToNameW** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

The maximum length of the network interface name, NDIS_IF_MAX_STRING_SIZE, without the terminating NULL character, is defined in the Ntddndis.h header file. The NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant, which is defined in the Ifdef.h header file.

> ⓘ Note
>
> The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

Use ConvertInterfaceLuidToNameA to convert a network interface LUID to an ANSI interface name.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Netioapi.h (include Netioapi.h)

The **ConvertInterfaceNameToLuidA** function converts an ANSI network interface name to the locally unique identifier (LUID) for the interface.

> ⓘ **Note**
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```C++
NETIOAPI_API ConvertInterfaceNameToLuidA(
  _In_  const CHAR     *InterfaceName,
  _Out_       NET_LUID *InterfaceLuid
);
```

Parameters

- *InterfaceName* [in]
  A pointer to a NULL-terminated ANSI string that contains the network interface name.

- *InterfaceLuid* [out]
  A pointer to the **NET_LUID** union for this interface.

Return value

ConvertInterfaceNameToLuidA returns STATUS_SUCCESS if the function succeeds. If the function fails, **ConvertInterfaceNameToLuidA** returns one of the following error codes:

Return code	Description

Return code	Description
ERROR_BUFFER_OVERFLOW	The length of the ANSI interface name is invalid. **ConvertInterfaceNameToLuidA** returns this error if the *InterfaceName* parameter exceeds the maximum allowed string length for this parameter.
STATUS_INVALID_NAME	The interface name is invalid. **ConvertInterfaceNameToLuidA** returns this error if the *InterfaceName* parameter contains an invalid interface name.
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceNameToLuidA** returns this error if the *InterfaceLuid* parameter is **NULL**.

Remarks

The **ConvertInterfaceNameToLuidA** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

The maximum length of the network interface name, NDIS_IF_MAX_STRING_SIZE, without the terminating **NULL**, is defined in the Ntddndis.h header file. NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant, which is defined in the Ifdef.h header file.

> ⓘ Note
>
> The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

Use the ConvertInterfaceNameToLuidW function to convert a Unicode interface name to a LUID.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

IRQL	PASSIVE_LEVEL

ConvertInterfaceNameToLuidW function

Article • 03/03/2023

The **ConvertInterfaceNameToLuidW** function converts a Unicode network interface name to the locally unique identifier (LUID) for the interface.

> **Note**
>
> The ConvertInterface*Xxx* API family enumerates identifiers over all interfaces bound to TCP/IP, which may include virtual miniports, lightweight filters, tunnel adapters, and physical interfaces.

Syntax

```c++
NETIOAPI_API ConvertInterfaceNameToLuidW(
  _In_  const WCHAR    *InterfaceName,
  _Out_       NET_LUID *InterfaceLuid
);
```

Parameters

- *InterfaceName* [in]
  A pointer to a NULL-terminated Unicode string that contains the network interface name.

- *InterfaceLuid* [out]
  A pointer to the NET_LUID union for this interface.

Return value

ConvertInterfaceNameToLuidW returns STATUS_SUCCESS if the function succeeds. If the function fails, **ConvertInterfaceNameToLuidW** returns one of the following error codes:

Return code	Description

Return code	Description
STATUS_INVALID_NAME	The interface name is invalid. **ConvertInterfaceNameToLuidW** returns this error if the *InterfaceName* parameter contains an invalid name or the length of the *InterfaceName* parameter exceeds the maximum allowed string length for this parameter.
STATUS_INVALID_PARAMETER	One of the parameters is invalid. **ConvertInterfaceNameToLuidW** returns this error if the *InterfaceLuid* parameter is **NULL**.

Remarks

The **ConvertInterfaceNameToLuidW** function is protocol-independent and works with network interfaces for both the IPv6 and IPv4 protocols.

The maximum length of the network interface name, NDIS_IF_MAX_STRING_SIZE, without the terminating NULL character, is defined in the Ntddndis.h header file. NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant, which is defined in the Ifdef.h header file.

> ⓘ Note
>
> The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

Use the ConvertInterfaceNameToLuidA function to convert an ANSI interface name to a LUID.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

ConvertIpv4MaskToLength function

Article • 03/03/2023

Reserved for future use. Do not use this function.

Syntax

C++

```
NETIOAPI_API ConvertIpv4MaskToLength(
  _In_  ULONG  Mask,
  _Out_ PUINT8 MaskLength
);
```

Parameters

- *Mask* [in]

  Reserved.

- *MaskLength* [out]

  Reserved.

Requirements

Header	Netioapi.h

ConvertLengthtoIpv4Mask function

Article • 03/03/2023

Reserved for future use. Do not use this function.

Syntax

```c++
NETIOAPI_API ConvertLengthtoIpv4Mask(
  _In_  ULONG  MaskLength,
  _Out_ PULONG Mask
);
```

Parameters

- *MaskLength* [in]

  Reserved.

- *Mask* [out]

  Reserved.

Requirements

Header	Netioapi.h

if_indextoname function

Article • 03/03/2023

The **if_indextoname** function converts the local index for a network interface to the ANSI interface name.

Syntax

```
C++

PCHAR NETIOAPI_API_ if_indextoname(
  _In_  NET_IFINDEX InterfaceIndex,
  _Out_ PCHAR       InterfaceName
);
```

Parameters

- *InterfaceIndex* [in]
  The local index for a network interface.

- *InterfaceName* [out]
  A pointer to a buffer to hold the NULL-terminated ANSI string. If **if_indextoname** succeeds, *InterfaceName* contains the ANSI interface name. The length, in bytes, of the buffer that this parameter points to must be equal to or greater than IF_NAMESIZE. For more information about IF_NAMESIZE, see the following Remarks section.

Return value

If this function succeeds, **if_indextoname** returns a pointer to a NULL-terminated ANSI string that contains the interface name. If this function fails, **if_indextoname** returns a **NULL** pointer

Remarks

The **if_indextoname** function maps an interface index into its corresponding name. This function is designed as part of basic socket extensions for IPv6, as described by the IETF in RFC 2553 .

The **if_indextoname** function is implemented for portability of drivers with Unix environments, but the **ConvertInterface*Xxx*** functions are the preferred method to convert network interface identifiers. You can replace the **if_indextoname** function by a call to the ConvertInterfaceIndexToLuid function to convert an interface index to a NET_LUID union, followed by a call to the ConvertInterfaceLuidToNameA function to convert NET_LUID to the ANSI interface name.

The length, in bytes, of the buffer that the *InterfaceName* parameter points to must be equal or greater than IF_NAMESIZE. The IF_NAMESIZE value is defined in the Netioapi.h header file as equal to NDIS_IF_MAX_STRING_SIZE. The maximum length of an interface name, NDIS_IF_MAX_STRING_SIZE, without the terminating NULL character is declared in the Ntddndis.h header file. The NDIS_IF_MAX_STRING_SIZE is defined to be the IF_MAX_STRING_SIZE constant that is defined in the Ifdef.h header file.

> ⓘ Note
>
> The *Ntddndis.h* and *Ifdef.h* header files are automatically included in the *Netioapi.h* header file. You should never use the *Ntddndis.h* and *Ifdef.h* header files directly.

If the **if_indextoname** function fails and returns a **NULL** pointer, you cannot determine an error code.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	PASSIVE_LEVEL

if_nametoindex function

Article • 03/03/2023

The **if_nametoindex** function converts the ANSI interface name for a network interface to the local index for the interface.

Syntax

```C++
NET_IFINDEX NETIOAPI_API_ if_nametoindex(
  _In_ PCSTR InterfaceName
);
```

Parameters

- *InterfaceName* [in]
  A pointer to a NULL-terminated ANSI string that contains the interface name.

Return value

If the function succeeds, **if_nametoindex** returns the local interface index. If the function fails, **if_nametoindex** returns zero.

Remarks

The **if_nametoindex** function maps an interface name into its corresponding index. This function is designed as part of basic socket extensions for IPv6 as described by the IETF in RFC 2553 .

The **if_nametoindex** function is implemented for portability of drivers with Unix environments, but the **ConvertInterface*Xxx*** functions are the preferred method to convert network interface identifiers. You can replace the **if_nametoindex** function by a call to the **ConvertInterfaceNameToLuidA** function to convert the ANSI interface name to a **NET_LUID** union, followed by a call to the **ConvertInterfaceLuidToIndex** function to convert NET_LUID to the local interface index.

If the **if_nametoindex** function fails and returns zero, you cannot determine an error code.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

GetIfEntry2 function

Article • 04/01/2024

The **GetIfEntry2** function retrieves information for the specified interface on a local computer.

> **Important**
>
> For driver developers, it is recommended to use GetIfEntry2Ex with MibIfEntryNormalWithoutStatistics when possible, in order to avoid a deadlock when servicing NDIS OIDs.

Syntax

C++

```
NETIOAPI_API GetIfEntry2(
  _Inout_ PMIB_IF_ROW2 Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IF_ROW2 structure that, on successful return, receives information for an interface on the local computer. On input, your driver must set the **InterfaceLuid** member or the **InterfaceIndex** member of the MIB_IF_ROW2 structure to the interface to retrieve information for.

Return value

GetIfEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIfEntry2** returns one of the following error codes:

Expand table

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the **MIB_IF_ROW2** structure that the *Row* parameter points to.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

On input, your driver must initialize at least the **InterfaceLuid** or **InterfaceIndex** member in the **MIB_IF_ROW2** structure that is passed in the *Row* parameter. The members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, the remaining fields of the MIB_IF_ROW2 structure that the *Row* parameter points to are filled in.

Requirements

Expand table

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

GetIfStackTable function

Article • 03/03/2023

The **GetIfStackTable** function retrieves a table of network interface stack row entries that specify the relationship of the network interfaces on an interface stack.

Syntax

```c++
NETIOAPI_API GetIfStackTable(
  _Out_ PMIB_IFSTACK_TABLE *Table
);
```

Parameters

- *Table* [out]
  A pointer to a buffer that receives the table of interface stack row entries in a MIB_IFSTACK_TABLE structure.

Return value

GetIfStackTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIfStackTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No interface stack entries were found.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIfStackTable** function enumerates the physical and logical network interfaces on an interface stack on a local computer and returns this information in a MIB_IFSTACK_TABLE structure.

Interface stack entries are returned in a MIB_IFSTACK_TABLE structure in the buffer that the *Table* parameter points to. The MIB_IFSTACK_TABLE structure contains an interface stack entry count and an array of MIB_IFSTACK_ROW structures for each interface stack entry.

The relationship between the interfaces in the interface stack is that the interface with index in the **HigherLayerInterfaceIndex** member of the MIB_IFSTACK_ROW structure is immediately above the interface with index in the **LowerLayerInterfaceIndex** member of the MIB_IFSTACK_ROW structure.

Memory is allocated by the **GetIfStackTable** function for the MIB_IFSTACK_TABLE structure and the MIB_IFSTACK_ROW entries in this structure. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Note that the returned MIB_IFSTACK_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IFSTACK_ROW array entry in the **Table** member of the MIB_IFSTACK_TABLE structure. Padding for alignment might also be present between the MIB_IFSTACK_ROW array entries. Any access to a MIB_IFSTACK_ROW array entry should assume padding may exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

GetIfTable2 function

Article • 03/03/2023

The **GetIfTable2** function retrieves the MIB-II interface table.

Syntax

```
C++

NETIOAPI_API GetIfTable2(
  _Out_ PMIB_IF_TABLE2 *Table
);
```

Parameters

- *Table* [out]

  A pointer to a buffer that receives the table of interfaces in a **MIB_IF_TABLE2** structure.

Return value

GetIfTable2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIfTable2** returns one of the following error codes:

Return code	Description
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIfTable2** function enumerates the logical and physical interfaces on a local computer and returns this information in a **MIB_IF_TABLE2** structure.

Your driver can use a similar function, **GetIfTable2Ex**, to specify the level of interfaces to return. A call to the **GetIfTable2Ex** function with the *Level* parameter set to

MibIfTableNormal retrieves the same results as calling the **GetIfTable2** function.

GetIfTable2 returns interfaces in a MIB_IF_TABLE2 structure in the buffer that the *Table* parameter points to. The MIB_IF_TABLE2 structure contains an interface count and an array of **MIB_IF_ROW2** structures for each interface. **GetIfTable2** allocates memory for the MIB_IF_TABLE2 structure and the MIB_IF_ROW2 entries in this structure. When these returned structures are no longer required, your driver should free the memory by calling **FreeMibTable**.

Note that the returned MIB_IF_TABLE2 structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IF_ROW2 array entry in the **Table** member of the MIB_IF_TABLE2 structure. Padding for alignment might also be present between the MIB_IF_ROW2 array entries. Any access to a MIB_IF_ROW2 array entry should assume padding may exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

GetIfTable2Ex

MIB_IF_TABLE2

MIB_IF_ROW2

GetIfTable2Ex function

Article • 03/03/2023

The **GetIfTable2Ex** function retrieves the MIB-II interface table, given a level of interface information to retrieve.

Syntax

```c++
NETIOAPI_API GetIfTable2Ex(
  _In_  MIB_IF_TABLE_LEVEL Level,
  _Out_ PMIB_IF_TABLE2     *Table
);
```

Parameters

- *Level* [in]
  The level of interface information to retrieve. This parameter can be one of the values from the MIB_IF_TABLE_LEVEL enumeration.

- *Table* [out]
  A pointer to a buffer that receives the table of interfaces in a MIB_IF_TABLE2 structure.

Return value

GetIfTable2Ex returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIfTable2Ex** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if an illegal value was passed in the *Level* parameter.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIfTable2Ex** function enumerates the logical and physical interfaces on a local computer and returns this information in a **MIB_IF_TABLE2** structure.

Your driver can use a similar function, **GetIfTable2**, to retrieve interfaces, but **GetIfTable2** does not enable your driver tospecify the level of interfaces to return. A call to the **GetIfTable2Ex** function with the *Level* parameter set to **MibIfTableNormal** retrieves the same results as calling the **GetIfTable2** function.

GetIfTable2Ex returns interfaces in a MIB_IF_TABLE2 structure in the buffer that the *Table* parameter points to. The MIB_IF_TABLE2 structure contains an interface count and an array of **MIB_IF_ROW2** structures for each interface. **GetIfTable2** allocates mmory for the MIB_IF_TABLE2 structure and the MIB_IF_ROW2 entries in this structure. When these returned structures are no longer required, your driver should free the memory by calling **FreeMibTable**.

All interfaces, including NDIS intermediate driver interfaces and NDIS filter driver interfaces, are returned for either of the possible values for the *Level* parameter. The setting for the *Level* parameter affects how statistics and state members of the MIB_IF_ROW2 structure in the MIB_IF_TABLE2 structure that is pointed to by the *Table* parameter for the interface are returned. For example, a network interface card (NIC) has an NDIS miniport driver. An NDIS intermediate driver can be installed to interface between upper-level protocol drivers and NDIS miniport drivers. An NDIS filter driver can be attached on top of the NDIS intermediate driver. Assume that the NIC reports the **MediaConnectState** member of the MIB_IF_ROW2 structure as **MediaConnectStateConnected**, but the NDIS filter driver modifies the state and reports the state as **MediaConnectStateDisconnected**. When the interface information is queried with *Level* parameter set to **MibIfTableNormal**, the state at the top of the filter stack (**MediaConnectStateDisconnected**) is reported. When the interface is queried with the *Level* parameter set to **MibIfTableRaw**, the state at the interface level directly (**MediaConnectStateConnected**) is returned.

Note that the returned MIB_IF_TABLE2 structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IF_ROW2 array entry in the **Table** member of the MIB_IF_TABLE2 structure. Padding for alignment might also be present between the MIB_IF_ROW2 array entries. Any access to a MIB_IF_ROW2 array entry should assume padding may exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

GetInvertedIfStackTable function

Article • 03/03/2023

The **GetInvertedIfStackTable** function retrieves a table of inverted network interface stack row entries that specify the relationship of the network interfaces on an interface stack.

Syntax

```c++
NETIOAPI_API GetInvertedIfStackTable(
  _Out_ PMIB_INVERTEDIFSTACK_TABLE *Table
);
```

Parameters

- *Table* [out]
  A pointer to a buffer that receives the table of inverted interface stack row entries in a MIB_INVERTEDIFSTACK_TABLE structure.

Return value

GetInvertedIfStackTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetInvertedIfStackTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No interface stack entries were found.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetInvertedIfStackTable** function enumerates the physical and logical network interfaces on an interface stack on a local computer and returns this information in an inverted form in the MIB_INVERTEDIFSTACK_TABLE structure.

GetInvertedIfStackTable returns interface stack entries in a MIB_INVERTEDIFSTACK_TABLE structure in the buffer that the *Table* parameter points to. The MIB_INVERTEDIFSTACK_TABLE structure contains an interface stack entry count and an array of MIB_INVERTEDIFSTACK_ROW structures for each interface stack entry.

The relationship between the interfaces in the interface stack is that the interface with index in the **HigherLayerInterfaceIndex** member of the MIB_INVERTEDIFSTACK_ROW structure is immediately above the interface with index in the **LowerLayerInterfaceIndex** member of the MIB_INVERTEDIFSTACK_ROW structure.

GetInvertedIfStackTable allocates memory for the MIB_INVERTEDIFSTACK_TABLE structure and the MIB_INVERTEDIFSTACK_ROW entries in this structure. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Note that the returned MIB_INVERTEDIFSTACK_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_INVERTEDIFSTACK_ROW array entry in the **Table** member of the MIB_INVERTEDIFSTACK_TABLE structure. Padding for alignment might also be present between the MIB_INVERTEDIFSTACK_ROW array entries. Any access to a MIB_INVERTEDIFSTACK_ROW array entry should assume padding might exist.

GetIpInterfaceTable function

Article • 03/03/2023

The **GetIpInterfaceTable** function retrieves the IP interface entries on a local computer.

Syntax

C++

```
NETIOAPI_API GetIpInterfaceTable(
  _In_  ADDRESS_FAMILY         Family,
  _Out_ PMIB_IPINTERFACE_TABLE *Table
);
```

Parameters

- *Family* [in]
  The address family of IP interfaces to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family.

  - AF_INET6
    The IPv6 address family.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, the **GetIpInterfaceTable** function returns the IP interface table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a buffer that receives the table of IP interface entries in a MIB_IPINTERFACE_TABLE structure.

Return value

GetIpInterfaceTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpInterfaceTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No IP interface entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The function is not supported. This error is returned when the IP transport that is specified in the *Address* parameter is not configured on the local computer. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpInterfaceTable** function enumerates the IP interfaces on a local computer and returns this information in an MIB_IPINTERFACE_TABLE structure.

GetIpInterfaceTable returns IP interface entries in a MIB_IPINTERFACE_TABLE structure in the buffer that the *Table* parameter points to. The MIB_IPINTERFACE_TABLE structure contains an IP interface entry count and an array of MIB_IPINTERFACE_ROW structures for each IP interface entry. When these returned structures are no longer required, your driver should free the memory by calling the FreeMibTable function.

Your driver must initialize the *Family* parameter to either AF_INET or AF_INET6.

Note that the returned MIB_IPINTERFACE_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first **MIB_IPINTERFACE_ROW** array entry in the **Table** member of the MIB_IPINTERFACE_TABLE structure. Padding for alignment might also be present between the MIB_IPINTERFACE_ROW array entries. Any access to a MIB_IPINTERFACE_ROW array entry should assume padding might exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IPNET_TABLE2

InitializeIpInterfaceEntry function

Article • 03/03/2023

The **InitializeIpInterfaceEntry** function initializes the members of an MIB_IPINTERFACE_ROW structure entry with default values.

Syntax

```
C++

VOID NETIOAPI_API_ InitializeIpInterfaceEntry(
  _Inout_ PMIB_IPINTERFACE_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPINTERFACE_ROW structure to initialize. On successful return, the fields in this parameter are initialized with default information for an interface on the local computer.

Return value

InitializeIpInterfaceEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **InitializeIpInterfaceEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

On output, the members of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to are initialized as follows.

- **Family**

  Set to AF_UNSPEC.

- **InterfaceLuid**

  Set to an unspecified value.

- All other members

  Set to zero.

Your driver must use the **InitializeIpInterfaceEntry** function to initialize the fields of a MIB_IPINTERFACE_ROW structure entry with default values. A driver can then change the fields in the MIB_IPINTERFACE_ROW entry that it wants to modify, and then call the SetIpInterfaceEntry function.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IPINTERFACE_TABLE

SetIpInterfaceEntry

SetIpInterfaceEntry function

Article • 03/03/2023

The **SetIpInterfaceEntry** function sets the properties of an IP interface on a local computer.

Syntax

```c++
NETIOAPI_API SetIpInterfaceEntry(
  _Inout_ PMIB_IPINTERFACE_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPINTERFACE_ROW structure entry for an interface. On input, your driver must set the **Family** member of the MIB_IPINTERFACE_ROW to AF_INET6 or AF_INET and your driver must specify the **InterfaceLuid** member or the **InterfaceIndex** member of MIB_IPINTERFACE_ROW. On a successful return, the **InterfaceLuid** member of the MIB_IPINTERFACE_ROW is filled in if the **InterfaceIndex** member of the MIB_IPINTERFACE_ROW entry was specified.

Return value

SetIpInterfaceEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **SetIpInterfaceEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Family** member of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to was not specified as AF_INET or AF_INET6, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPINTERFACE_ROW structure were unspecified.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must use the **InitializeIpInterfaceEntry** function to initialize the fields of a **MIB_IPINTERFACE_ROW** structure entry with default values. A driver can then change the fields in the MIB_IPINTERFACE_ROW entry that it wants to modify, and then call the **SetIpInterfaceEntry** function.

On input, your driver must initialize the following members of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to.

- **Family**
  Set to either AF_INET or AF_INET6.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, the **InterfaceLuid** member of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to is filled in if the **InterfaceIndex** was specified.

SetIpInterfaceEntry ignores the **MaxReassemblySize**, **MinRouterAdvertisementInterval**, **MaxRouterAdvertisementInterval**, **Connected**, **SupportsWakeUpPatterns**, **SupportsNeighborDiscovery**, **SupportsRouterDiscovery**, **ReachableTime**, **TransmitOffload**, and **ReceiveOffload** members of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to. These members are set by the network stack and cannot be changed by using the **SetIpInterfaceEntry** function.

Unprivileged simultaneous access to multiple networks of different security requirements creates a security hole and enables an unprivileged driver to accidentally relay data between the two networks. A typical example is simultaneous access to a virtual private network (VPN) and the Internet. The Windows Server 2003 and Windows

XP operating systems use a weak host model, where Remote Access Service (RAS) prevents such simultaneous access by increasing the route metric of all default routes over other interfaces. Therefore, all traffic is routed through the VPN interface, disrupting other network connectivity.

On Windows Vista and later versions of the Windows operating systems, by default, a strong host model is used. If a source IP address is specified in the route lookup by using the GetBestRoute2 function, the route lookup is restricted to the interface of the source IP address. The route metric modification by RAS has no effect because the list of potential routes does not even have the route for the VPN interface, which enables traffic to the Internet. Your driver can use the **DisableDefaultRoutes** member of the MIB_IPINTERFACE_ROW structure to disable using the default route on an interface. VPN clients can use this member as a security measure to restrict split tunneling when split tunneling is not required by the VPN client. A VPN client can call the **SetIpInterfaceEntry** function to set the **DisableDefaultRoutes** member to **TRUE** when it is required. A VPN client can query the current state of the **DisableDefaultRoutes** member by calling the **GetIpInterfaceEntry** function.

CreateAnycastIpAddressEntry function

Article • 03/03/2023

The **CreateAnycastIpAddressEntry** function adds a new anycast IP address entry on a local computer.

Syntax

```C++
NETIOAPI_API CreateAnycastIpAddressEntry(
  _In_ const MIB_ANYCASTIPADDRESS_ROW *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_ANYCASTIPADDRESS_ROW structure entry for an anycast IP address entry.

Return value

CreateAnycastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CreateAnycastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_ANYCASTIPADDRESS_ROW structure were unspecified.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
ERROR_OBJECT_ALREADY_EXISTS	The object already exists. This error is returned if the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to is a duplicate of an existing anycast IP address on the interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_ANYCASTIPADDRESS_ROW structure.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must initialize the following members of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface to add the unicast IP address to. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

The **ScopeId** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to is ignored when the **CreateAnycastIpAddressEntry** function is called. The **ScopeId** member is automatically determined by the interface that the address is added on.

The **CreateAnycastIpAddressEntry** function fails if the anycast IP address that is passed in the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to is a duplicate of an existing anycast IP address on the interface.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

CreateSortedAddressPairs function

Article • 03/03/2023

From a supplied list of potential IP destination addresses, the **CreateSortedAddressPairs** function pairs the destination addresses together with the host machine's local IP addresses and sorts the pairs according to the preferred order of communication.

Syntax

C++

```
NETIOAPI_API CreateSortedAddressPairs(
  _In_opt_ const PSOCKADDR_IN6      SourceAddressList,
  _In_           ULONG              SourceAddressCount,
  _In_     const PSOCKADDR_IN6      DestinationAddressList,
  _In_           ULONG              DestinationAddressCount,
  _In_           ULONG              AddressSortOptions,
  _In_           PSOCKADDR_IN6_PAIR *SortedAddressPairList,
  _Out_          ULONG              *SortedAddressPairCount
);
```

Parameters

- *SourceAddressList* [in, optional]

  Reserved. This parameter must be **NULL**.

- *SourceAddressCount* [in]

  Reserved. This parameter must be zero.

- *DestinationAddressList* [in]

  A pointer to a list of potential destination addresses of type **SOCKADDR_IN6**.

- *DestinationAddressCount* [in]

  The number of addresses in the list that the *DestinationAddressList* parameter points to.

- *AddressSortOptions* [in]

  Reserved. This parameter must be zero.

- *SortedAddressPairList* [in]

  A pointer to a list of pairs of source and destination addresses, sorted in the preferred order of communication. For more information about this parameter, see the following Remarks section.

- *SortedAddressPairCount* [out]
  The number of address pairs in the list that the *SortedAddressPairList* parameter points to.

Return value

CreateSortedAddressPairs returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CreateSortedAddressPairs** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources were available to complete the operation.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **CreateSortedAddressPairs** function automatically pairs the host machine's local addresses together with the supplied list of potential destination addresses that the *DestinationAddressList* parameter points to.

The returned list of pairs of addresses that the *SortedAddressPairList* parameter points to is sorted so that the address pairs that are best suited for communication between two peers occurr earlier in the list.

The *SortedAddressPairList* parameter is of type PSOCKADDR_IN6_PAIR, which is defined in the Ws2ipdef.h header as follows.

```C++

    typedef struct _sockaddr_in6_pair
    {
        PSOCKADDR_IN6  SourceAddress;
        PSOCKADDR_IN6  DestinationAddress;
    } SOCKADDR_IN6_PAIR, *PSOCKADDR_IN6_PAIR;

  - **SourceAddress**
    The IP source address.
  - **DestinationAddress**
    The IP destination address.
```

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

SOCKADDR_IN6

CreateUnicastIpAddressEntry function

Article • 03/03/2023

The **CreateUnicastIpAddressEntry** function adds a new unicast IP address entry on the local computer.

Syntax

```C++
NETIOAPI_API CreateUnicastIpAddressEntry(
  _In_ const MIB_UNICASTIPADDRESS_ROW *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_UNICASTIPADDRESS_ROW structure entry for a unicast IP address entry.

Return value

CreateUnicastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CreateUnicastIpAddressEntry** returns one of the following error codes:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_UNICASTIPADDRESS_ROW structure were unspecified. This error is also returned for other errors in the values that are set for members in the MIB_UNICASTIPADDRESS_ROW structure. These errors include the following situations: • The **ValidLifetime** member is less than than the **PreferredLifetime** member. • The **PrefixOrigin** member is set to **IpPrefixOriginUnchanged** and the **SuffixOrigin** is not set to IpSuffixOriginUnchanged. • The **PrefixOrigin** member is not set to **IpPrefixOriginUnchanged** and the **SuffixOrigin** is set to IpSuffixOriginUnchanged. • The **PrefixOrigin** member is not set to a value from the NL_PREFIX_ORIGIN enumeration. • The **SuffixOrigin** member is not set to a value from the NL_SUFFIX_ORIGIN enumeration. • The **OnLinkPrefixLength** member is set to a value that is greater than the IP address length, in bits (32 for a unicast IPv4 address or 128 for a unicast IPv6 address). For possible values of the NL_PREFIX_ORIGIN and NL_SUFFIX_ORIGIN enumerations, see MIB_UNICASTIPADDRESS_ROW.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.

Return code	Description
ERROR_OBJECT_ALREADY_EXISTS	The object already exists. This error is returned if the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to is a duplicate of an existing unicast IP address on the interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Use the InitializeUnicastIpAddressEntry function to initialize the members of a MIB_UNICASTIPADDRESS_ROW structure entry with default values. A driver can then change the members in the MIB_UNICASTIPADDRESS_ROW entry that it wants to modify, and then call the **CreateUnicastIpAddressEntry** function.

On input, your driver must initialize the following members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface to add the unicast IP address to. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

If the **OnLinkPrefixLength** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to is set to 255, **CreateUnicastIpAddressEntry** adds the new unicast IP address with the **OnLinkPrefixLength** member set equal to the length of the IP address. So for a unicast IPv4 address, the **OnLinkPrefixLength** is set to 32 and the **OnLinkPrefixLength** is set to 128 for a unicast IPv6 address. If this setting would result in the incorrect subnet mask for an IPv4 address or the incorrect link prefix for an IPv6 address, the driver should set the **OnLinkPrefixLength** member to the correct value before calling **CreateUnicastIpAddressEntry**.

If a unicast IP address is created with the **OnLinkPrefixLength** member set incorrectly, your driver can change the IP address by calling SetUnicastIpAddressEntry with the **OnLinkPrefixLength** member set to the correct value.

The **DadState**, **ScopeId**, and **CreationTimeStamp** members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to are ignored when the **CreateUnicastIpAddressEntry** function is called. These members are set by the network stack. The **ScopeId** member is automatically determined by the interface that the address is added on.

The **CreateUnicastIpAddressEntry** function fails if the unicast IP address that is passed in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to is a duplicate of an existing unicast IP address on the interface. Note that your driver can add a loopback IP address to a loopback interface only by using the **CreateUnicastIpAddressEntry** function.

The unicast IP address that is passed in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to is not usable immediately. The IP address is usable after the duplicate address detection process has completed successfully. It can take several seconds for the duplicate address detection process to complete because IP packets must be sent and potential responses must be waited for. For IPv6, the duplicate address detection process typically takes about 1 second. For IPv4, the duplicate address detection process typically takes about 3 seconds.

After a driver calls the **CreateUnicastIpAddressEntry** function, it can use the following methods to determine if an IP address is still usable:

- **Use polling and the GetUnicastIpAddressEntry function**
  After the call to the **CreateUnicastIpAddressEntry** function returns successfully, pause for 1 to 3 seconds (depending on whether an IPv6 or IPv4 address is being created) to allow time for the successful completion of the duplication address detection process. Then, call **GetUnicastIpAddressEntry** to retrieve the updated MIB_UNICASTIPADDRESS_ROW structure and examine the value of the **DadState** member. If the value of the **DadState** member is set to IpDadStatePreferred, the IP address is now usable. If the value of the **DadState** member is set to IpDadStateTentative, duplicate address detection has not yet completed. In this case, call the **GetUnicastIpAddressEntry** function again every 0.5 seconds while the **DadState** member is still set to IpDadStateTentative. If the value of the **DadState** member returns with some value other than **IpDadStatePreferred** or IpDadStateTentative, duplicate address detection has failed and the IP address is not usable.

- **Call one of the IP Helper NotifyXxx notification functions to set up an asynchronous notification for when an address changes**
  After the call to the **CreateUnicastIpAddressEntry** function returns successfully, call

the NotifyUnicastIpAddressChange function to register the driver to be notified of changes to either IPv6 or IPv4 unicast IP addresses, depending on the type of IP address that is being created. When a notification is received for the IP address that is being created, call the **GetUnicastIpAddressEntry** function to retrieve the **DadState** member. If the value of the **DadState** member is set to IpDadStatePreferred, the IP address is now usable. If the value of the **DadState** member is set to IpDadStateTentative, duplicate address detection has not yet completed and the driver must wait for future notifications. If the value of the **DadState** member returns with some value other than **IpDadStatePreferred** or IpDadStateTentative, duplicate address detection has failed and the IP address is not usable.

If, during the duplicate address detection process, the media is disconnected and then reconnected, the duplicate address detection process is restarted. So the time to complete the process might increase beyond the typical 1 second value for IPv6 or 3 second value for IPv4.

DeleteAnycastIpAddressEntry function

Article • 03/03/2023

The **DeleteAnycastIpAddressEntry** function deletes an existing anycast IP address entry on a local computer.

Syntax

```C++
NETIOAPI_API DeleteAnycastIpAddressEntry(
  _In_ const MIB_ANYCASTIPADDRESS_ROW *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_ANYCASTIPADDRESS_ROW structure entry for an existing anycast IP address entry to delete from the local computer.

Return value

DeleteAnycastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **DeleteAnycastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_ANYCASTIPADDRESS_ROW structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **DeleteAnycastIpAddressEntry** function is used to delete an existing MIB_ANYCASTIPADDRESS_ROW structure entry on the local computer.

On input, your driver must initialize the following members of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

If the function is successful, the existing IP address that the *Row* parameter represents was deleted.

Your driver can call the **GetAnycastIpAddressTable** function to enumerate the anycast IP address entries on a local computer. Your driver can call the **GetAnycastIpAddressEntry** function to retrieve a specific existing anycast IP address entry.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

The **DeleteUnicastIpAddressEntry** function deletes an existing unicast IP address entry on a local computer.

Syntax

C++

```
NETIOAPI_API DeleteUnicastIpAddressEntry(
  _In_ const MIB_UNICASTIPADDRESS_ROW *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_UNICASTIPADDRESS_ROW structure entry for an existing unicast IP address entry to delete from the local computer.

Return value

DeleteUnicastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **DeleteUnicastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_UNICASTIPADDRESS_ROW structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **DeleteUnicastIpAddressEntry** function is used to delete an existing **MIB_UNICASTIPADDRESS_ROW** structure entry on the local computer.

On input, your driver must initialize the following members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid IPv4 or IPv6 unicast address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

If the function is successful, the existing IP address that the *Row* parameter represents is deleted.

Your driver can call the **GetUnicastIpAddressTable** function to enumerate the unicast IP address entries on a local computer. Your driver can call the **GetUnicastIpAddressEntry** function to retrieve a specific existing unicast IP address entry.

GetAnycastIpAddressEntry function

Article • 03/03/2023

The **GetAnycastIpAddressEntry** function retrieves information for an existing anycast IP address entry on a local computer.

Syntax

```C++
NETIOAPI_API GetAnycastIpAddressEntry(
  _Inout_ PMIB_ANYCASTIPADDRESS_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_ANYCASTIPADDRESS_ROW structure entry for an anycast IP address entry. On successful return, this structure is updated with the properties for an existing anycast IP address.

Return value

GetAnycastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetAnycastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid anycast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_ANYCASTIPADDRESS_ROW structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetAnycastIpAddressEntry** function is used to retrieve an existing MIB_ANYCASTIPADDRESS_ROW structure entry.

On input, your driver must initialize the following members of the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid IPv4 or IPv6 anycast address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetAnycastIpAddressEntry** retrieves the other properties for the anycast IP address and fills out the MIB_ANYCASTIPADDRESS_ROW structure that the *Row* parameter points to.

Your driver can call the GetAnycastIpAddressTable function to enumerate the anycast IP address entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

GetAnycastIpAddressTable function

Article • 03/03/2023

The **GetAnycastIpAddressTable** function retrieves the anycast IP address table on a local computer.

Syntax

```c++
NETIOAPI_API GetAnycastIpAddressTable(
  _In_  ADDRESS_FAMILY             Family,
  _Out_ PMIB_ANYCASTIPADDRESS_TABLE *Table
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameterare defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function returns the anycast IP address table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function returns the anycast IP address table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function

returns the anycast IP address table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a MIB_ANYCASTIPADDRESS_TABLE structure that contains a table of anycast IP address entries on the local computer.

Return value

GetAnycastIpAddressTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetAnycastIpAddressTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No anycast IP address entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetAnycastIpAddressTable** function enumerates the anycast IP addresses on a local computer and returns this information in a MIB_ANYCASTIPADDRESS_TABLE structure.

The anycast IP address entries are returned in a MIB_ANYCASTIPADDRESS_TABLE structure in the buffer that the *Table* parameter points to. The MIB_ANYCASTIPADDRESS_TABLE structure contains an anycast IP address entry count and an array of MIB_ANYCASTIPADDRESS_ROW structures for each anycast IP address entry. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_ANYCASTIPADDRESS_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_ANYCASTIPADDRESS_ROW array entry in the **Table** member of the MIB_ANYCASTIPADDRESS_TABLE structure. Padding for alignment might also be present between the MIB_ANYCASTIPADDRESS_ROW array entries. Any access to a MIB_ANYCASTIPADDRESS_ROW array entry should assume padding may exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

MIB_ANYCASTIPADDRESS_ROW

MIB_ANYCASTIPADDRESS_TABLE

GetMulticastIpAddressEntry function

Article • 03/03/2023

The **GetMulticastIpAddressEntry** function retrieves information for an existing multicast IP address entry on a local computer.

Syntax

```c++
NETIOAPI_API GetMulticastIpAddressEntry(
  _Inout_ PMIB_MULTICASTIPADDRESS_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_MULTICASTIPADDRESS_ROW structure entry for a multicast IP address entry. On successful return, this structure is updated with the properties for an existing multicast IP address.

Return value

GetMulticastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetMulticastIpAddressEntry** returns one of the following error codes:

Return code	**Description**
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_MULTICASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid multicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_MULTICASTIPADDRESS_ROW structure were unspecified.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_MULTICASTIPADDRESS_ROW structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_MULTICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetMulticastIpAddressEntry** function is used to retrieve an existing MIB_MULTICASTIPADDRESS_ROW structure entry.

On input, your driver must initialize the following members of the MIB_MULTICASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetMulticastIpAddressEntry** retrieves the other properties for the multicast IP address and fills in the MIB_MULTICASTIPADDRESS_ROW structure that the *Row* parameter points to.

Your driver can call the **GetMulticastIpAddressTable** function to enumerate the multicast IP address entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

MIB_MULTICASTIPADDRESS_TABLE

GetMulticastIpAddressTable function

Article • 03/03/2023

The **GetMulticastIpAddressTable** function retrieves the multicast IP address table on a local computer.

Syntax

```c++
NETIOAPI_API GetMulticastIpAddressTable(
  _In_  ADDRESS_FAMILY                Family,
  _Out_ PMIB_MULTICASTIPADDRESS_TABLE *Table
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function returns the multicast IP address table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function returns the multicast IP address table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function

returns the multicast IP address table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a MIB_MULTICASTIPADDRESS_TABLE structure that contains a table of anycast IP address entries on the local computer.

Return value

GetMulticastIpAddressTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetMulticastIpAddressTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No anycast IP address entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetMulticastIpAddressTable** function enumerates the multicast IP addresses on a local computer and returns this information in a MIB_MULTICASTIPADDRESS_TABLE structure.

GetMulticastIpAddressTable returns the multicast IP address entries in a MIB_MULTICASTIPADDRESS_TABLE structure in the buffer that the *Table* parameter points to. The MIB_MULTICASTIPADDRESS_TABLE structure contains a multicast IP address entry count and an array of MIB_MULTICASTIPADDRESS_ROW structures for each multicast IP address entry. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_MULTICASTIPADDRESS_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_MULTICASTIPADDRESS_ROW array entry in the **Table** member of the MIB_MULTICASTIPADDRESS_TABLE structure. Padding for alignment might also be present between the MIB_MULTICASTIPADDRESS_ROW array entries. Any access to a MIB_MULTICASTIPADDRESS_ROW array entry should assume padding might exist.

GetUnicastIpAddressEntry function

Article • 03/03/2023

The **GetUnicastIpAddressEntry** function retrieves information for an existing unicast IP address entry on a local computer.

Syntax

```c++
NETIOAPI_API GetUnicastIpAddressEntry(
  _Inout_ PMIB_UNICASTIPADDRESS_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_UNICASTIPADDRESS_ROW structure entry for a unicast IP address entry. On successful return, this structure is updated with the properties for an existing unicast IP address.

Return value

GetUnicastIpAddressEntry returns **STATUS_SUCCESS** if the function succeeds.

If the function fails, **GetUnicastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the **MIB_UNICASTIPADDRESS_ROW** structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetUnicastIpAddressEntry** function is typically used to retrieve an existing **MIB_UNICASTIPADDRESS_ROW** structure entry to be modified. A driver can then change the members in the **MIB_UNICASTIPADDRESS_ROW** entry that it wants to modify, and then call the **SetUnicastIpAddressEntry** function.

On input, your driver must initialize the following members of the **MIB_UNICASTIPADDRESS_ROW** structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetUnicastIpAddressEntry** retrieves the other properties for the unicast IP address and fills in the **MIB_UNICASTIPADDRESS_ROW** structure that the *Row* parameter points to.

Your driver can call the **GetUnicastIpAddressTable** function to enumerate the unicast IP address entries on a local computer.

Requirements

Target platform	Universal

Version	Available in Windows Vista and later versions of the Windows operating systems.

GetUnicastIpAddressTable function

Article • 03/03/2023

The **GetUnicastIpAddressTable** function retrieves the unicast IP address table on a local computer.

Syntax

```
C++

NETIOAPI_API GetUnicastIpAddressTable(
  _In_  ADDRESS_FAMILY             Family,
  _Out_ PMIB_UNICASTIPADDRESS_TABLE *Table
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function returns the multicast IP address table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function returns the multicast IP address table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function

returns the multicast IP address table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a MIB_UNICASTIPADDRESS_TABLE structure that contains a table of unicast IP address entries on the local computer.

Return value

GetUnicastIpAddressTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetUnicastIpAddressTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No unicast IP address entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetUnicastIpAddressTable** function enumerates the unicast IP addresses on a local computer and returns this information in an MIB_UNICASTIPADDRESS_TABLE structure.

GetUnicastIpAddressTable returns the unicast IP address entries in a MIB_UNICASTIPADDRESS_TABLE structure in the buffer that the *Table* parameter points to. The MIB_UNICASTIPADDRESS_TABLE structure contains a unicast IP address entry count and an array of MIB_UNICASTIPADDRESS_ROW structures for each unicast IP address entry. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_UNICASTIPADDRESS_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_UNICASTIPADDRESS_ROW array entry in the **Table** member of the MIB_UNICASTIPADDRESS_TABLE structure. Padding for alignment might also be present between the MIB_UNICASTIPADDRESS_ROW array entries. Any access to a MIB_UNICASTIPADDRESS_ROW array entry should assume padding might exist.

SetUnicastIpAddressEntry

InitializeUnicastIpAddressEntry function

Article • 03/03/2023

The **InitializeUnicastIpAddressEntry** function initializes a MIB_UNICASTIPADDRESS_ROW structure with default values for a unicast IP address entry on a local computer.

Syntax

```c++
VOID NETIOAPI_API_ InitializeUnicastIpAddressEntry(
  _Out_ PMIB_UNICASTIPADDRESS_ROW Row
);
```

Parameters

- *Row* [out]
  On entry, a pointer to a MIB_UNICASTIPADDRESS_ROW structure entry for a unicast IP address entry. On return, the MIB_UNICASTIPADDRESS_ROW structure that this parameter points to is initialized with default values for a unicast IP address.

Return value

None

Remarks

Your driver must use the **InitializeUnicastIpAddressEntry** function to initialize the members of a MIB_UNICASTIPADDRESS_ROW structure entry with default values for a unicast IP address for later use with the CreateUnicastIpAddressEntry function.

On input, your driver must pass **InitializeUnicastIpAddressEntry** a new MIB_UNICASTIPADDRESS_ROW structure to initialize.

On output, the members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to are initialized as follows.

- PrefixOrigin

  Set to the **IpPrefixOriginUnchanged** value of the NL_PREFIX_ORIGIN enumeration.

- SuffixOrigin

  Set to the **IpSuffixOriginUnchanged** value of the NL_PREFIX_ORIGIN enumeration.

- OnLinkPrefixLength

  Set to an illegal value.

- **PreferredLifetime** and **ValidLifetime**

  Set to infinite values.

- SkipAsSource

  Set to **FALSE**.

- All other members

  Set to zero.

After a driver calls **InitializeUnicastIpAddressEntry**, the driver can then change the members in the MIB_UNICASTIPADDRESS_ROW entry that it wants to modify, and then call the **CreateUnicastIpAddressEntry** to add the new unicast IP address to the local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

SetUnicastIpAddressEntry

SetUnicastIpAddressEntry function

Article • 03/03/2023

The **SetUnicastIpAddressEntry** function sets the properties of an existing unicast IP address entry on a local computer.

Syntax

```c++
NETIOAPI_API SetUnicastIpAddressEntry(
  _In_ const MIB_UNICASTIPADDRESS_ROW *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_UNICASTIPADDRESS_ROW structure entry for an existing unicast IP address entry.

Return value

SetUnicastIpAddressEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **SetUnicastIpAddressEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to was not set to a valid unicast IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_UNICASTIPADDRESS_ROW structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetUnicastIpAddressEntry** function is typically used to retrieve an existing **MIB_UNICASTIPADDRESS_ROW** structure entry to be modified. A driver can then change the members in the MIB_UNICASTIPADDRESS_ROW entry that it wants to modify, and then call the **SetUnicastIpAddressEntry** function.

A driver can call the **InitializeUnicastIpAddressEntry** function to initialize the members of a MIB_UNICASTIPADDRESS_ROW structure entry with default values before making changes. However, the driver typically saves either the **InterfaceLuid** or **InterfaceIndex** member before calling **InitializeUnicastIpAddressEntry** and restores one of these members after the call.

Your driver must initialize the following members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

If the **OnLinkPrefixLength** member of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to is set to 255, **SetUnicastIpAddressEntry** sets the unicast IP address properties so that the **OnLinkPrefixLength** member is equal to the length of the IP address. For a unicast IPv4 address, **OnLinkPrefixLength** is set to 32. For a unicast IPv6 address, **OnLinkPrefixLength** is set to 128. If these settings would result in the incorrect subnet mask for an IPv4 address or the incorrect link prefix for an IPv6 address, the driver should set this member to the correct value before calling **SetUnicastIpAddressEntry**.

SetUnicastIpAddressEntry ignores the **DadState**, **ScopeId**, and **CreationTimeStamp** members of the MIB_UNICASTIPADDRESS_ROW structure that the *Row* parameter points to. These members are set by the network stack and cannot be changed by using the **SetUnicastIpAddressEntry** function. The **ScopeId** member is automatically determined by the interface that the address was added on.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

CreateIpNetEntry2 function

Article • 03/03/2023

The **CreateIpNetEntry2** function creates a new neighbor IP address entry on the local computer.

Syntax

```
C++

NETIOAPI_API CreateIpNetEntry2(
  _In_ const MIB_IPNET_ROW2 *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_IPNET_ROW2 structure entry for an IP route entry.

Return value

CreateIpNetEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CreateIpNetEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if one of the following items occurs: • A **NULL** pointer is passed in the *Row* parameter. • The **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to was not set to a valid unicast, anycast, or multicast IPv4 or IPv6 address. • The **PhysicalAddress** and **PhysicalAddressLength** members of the MIB_IPNET_ROW2 structure were not set to a valid physical address. • Both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPNET_ROW2 structure were unspecified. • A loopback address was passed in the **Address** member.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
ERROR_OBJECT_ALREADY_EXISTS	The object already exists. This error is returned if the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to is a duplicate of an existing neighbor IP address on the interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must initialize the following members of the **MIB_IPNET_ROW2** structure that the *Row* parameter points to:

- Set the **Address** member to a valid unicast, anycast, or multicast IPv4 or IPv6 address and family.
- Set the **PhysicalAddress** and **PhysicalAddressLength** members in the MIB_IPNET_ROW2 structure to a valid physical address.
- Set **InterfaceLuid** or **InterfaceIndex** to the LUID or index value of the interface.

The **InterfaceLuid** and **InterfaceIndex** members are used in the order that is listed earlier. So if the **InterfaceLuid** is specified, this member is used to determine the interface to add the unicast IP address on. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

The **CreateIpNetEntry2** function fails if the IP address that is passed in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to is a duplicate of an existing neighbor IP address on the interface.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

DeleteIpNetEntry2 function

Article • 03/03/2023

The **DeleteIpNetEntry2** function deletes a neighbor IP address entry on a local computer.

Syntax

C++

```
NETIOAPI_API DeleteIpNetEntry2(
  _In_ const MIB_IPNET_ROW2 *Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_IPNET_ROW2 structure entry for a neighbor IP address entry. On successful return, this entry is deleted.

Return value

DeleteIpNetEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **DeleteIpNetEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to was not set to a valid neighbor IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPNET_ROW2 structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **DeleteIpNetEntry2** function is used to delete a **MIB_IPNET_ROW2** structure entry.

On input, your driver must initialize the following members of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

- **Address**
  Set to a valid neighbor IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **DeleteIpNetEntry2** deletes the neighbor IP address.

Your driver can call the **GetIpNetTable2** function to enumerate the neighbor IP address entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

SetIpNetEntry2

FlushIpNetTable2 function

Article • 03/03/2023

The **FlushIpNetTable2** function flushes the IP neighbor table on a local computer.

Syntax

C++

```
NETIOAPI_API FlushIpNetTable2(
  _In_ ADDRESS_FAMILY Family,
  _In_ NET_IFINDEX    InterfaceIndex
);
```

Parameters

- *Family* [in]

  The address family to flush.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET

    The IPv4 address family. When this value is specified, this function flushes the neighbor IP address table that contains only IPv4 entries.

  - AF_INET6

    The IPv6 address family. When this value is specified, this function flushes the neighbor IP address table that contains only IPv6 entries.

  - AF_UNSPEC

    The address family is unspecified. When this value is specified, this function flushes the neighbor IP address table that contains both IPv4 and IPv6 entries.

- *InterfaceIndex* [in]
  The interface index. If the index is specified, the function flushes the neighbor IP address entries on a specific interface.Ootherwise, the function flushes the neighbor IP address entries on all the interfaces. To ignore the interface, set this parameter to zero.

Return value

FlushIpNetTable2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **FlushIpNetTable2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **FlushIpNetTable2** function flushes or deletes the neighbor IP addresses on a local computer. Your driver can use the *Family* parameter to limit neighbor IP addresses to delete to a particular IP address family. If neighbor IP addresses for both IPv4 and IPv6 should be deleted, your driver should set the *Family* parameter to AF_UNSPEC. Your driver can use the *InterfaceIndex* parameter to limit neighbor IP addresses to delete to a particular interface. If neighbor IP addresses for all interfaces should be deleted, your driver should set the *InterfaceIndex* parameter to zero.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

SetIpNetEntry2

GetIpNetEntry2 function

Article • 03/03/2023

The **GetIpNetEntry2** function retrieves information for a neighbor IP address entry on the local computer.

Syntax

```c++
NETIOAPI_API GetIpNetEntry2(
  _Inout_ PMIB_IPNET_ROW2 Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPNET_ROW2 structure entry for a neighbor IP address entry. On successful return, this structure is updated with the properties for neighbor IP address.

Return value

GetIpNetEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpNetEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to was not set to a valid neighbor IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPNET_ROW2 structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpNetEntry2** function is used to retrieve a **MIB_IPNET_ROW2** structure entry.

On input, your driver must initialize the following members of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

- **Address**
  Set to a valid neighbor IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetIpNetEntry2** retrieves the other properties for the neighbor IP address and fills in the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

Your driver can call the **GetIpNetTable2** function to enumerate the neighbor IP address entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

Library	Netio.lib
IRQL	< DISPATCH_LEVEL

GetIpNetTable2

MIB_IPNET_ROW2

GetIpNetTable2 function

Article • 03/03/2023

The **GetIpNetTable2** function retrieves the IP neighbor table on a local computer.

Syntax

```c++
NETIOAPI_API GetIpNetTable2(
  _In_  ADDRESS_FAMILY    Family,
  _Out_ PMIB_IPNET_TABLE2 *Table
);
```

Parameters

- *Family* [in]

  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET

    The IPv4 address family. When this value is specified, this function returns the neighbor IP address table that contains only IPv4 entries.

  - AF_INET6

    The IPv6 address family. When this value is specified, this function returns the neighbor IP address table that contains only IPv6 entries.

  - AF_UNSPEC

    The address family is unspecified. When this value is specified, this function returns the neighbor IP address table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a **MIB_IPNET_TABLE2** structure that contains a table of neighbor IP address entries on the local computer.

Return value

GetIpNetTable2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpNetTable2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No neighbor IP address entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpNetTable2** function enumerates the neighbor IP addresses on a local computer and returns this information in a **MIB_IPNET_TABLE2** structure.

GetIpNetTable2 returns the neighbor IP address entries in a MIB_IPNET_TABLE2 structure in the buffer that the *Table* parameter points to. The MIB_IPNET_TABLE2 structure contains a neighbor IP address entry count and an array of **MIB_IPNET_ROW2** structures for each neighbor IP address entry. When these returned structures are no longer required, your driver should free the memory by calling **FreeMibTable**.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_IPNET_TABLE2 structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IPNET_ROW2 array entry in the **Table** member of the MIB_IPNET_TABLE2 structure. Padding for alignment might also be present between the MIB_IPNET_ROW2 array entries. Any access to a MIB_IPNET_ROW2 array entry should assume padding might exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

GetIpNetEntry2

MIB_IPNET_ROW2

MIB_IPNET_TABLE2

ResolveIpNetEntry2

SetIpNetEntry2

ResolveIpNetEntry2 function

Article • 03/03/2023

The **ResolveIpNetEntry2** function resolves the physical address for a neighbor IP address entry on a local computer.

Syntax

```c++
NETIOAPI_API ResolveIpNetEntry2(
  _Inout_        PMIB_IPNET_ROW2 Row,
  _In_opt_ const SOCKADDR_INET   *SourceAddress
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPNET_ROW2 structure entry for a neighbor IP address entry. On successful return, this structure is updated with the properties for neighbor IP address.

- *SourceAddress* [in, optional]
  A pointer to an optional source IP address that is used to select the interface to send the requests on for the neighbor IP address entry.

Return value

ResolveIpNetEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **ResolveIpNetEntry2** returns one of the following error codes:

Return code	Description
STATUS_BAD_NETWORK_NAME	The network name cannot be found. This error is returned if the network with the neighbor IP address is unreachable.

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to was not set to a valid IPv4 or IPv6 address, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPNET_ROW2 structure were unspecified. This error is also returned if a loopback address was passed in the **Address** member.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **ResolveIpNetEntry2** function is used to resolve the physical address for a neighbor IP address entry on a local computer. This function flushes any existing neighbor entry that matches the IP address on the interface and then resolves the physical address (MAC) address by sending ARP requests for an IPv4 address or Neighbor Solicitation (NS) requests for an IPv6 address. If the *SourceAddress* parameter is specified, **ResolveIpNetEntry2** selects the interface with this source IP address to send the requests on. If the *SourceAddress* parameter is not specified (**NULL** was passed in this parameter), **ResolveIpNetEntry2** automatically selects the best interface to send the requests on.

Your driver must initialize the following members of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

- **Address**
  Set to a valid IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

If the IP address that is passed in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to is a duplicate of an existing neighbor IP address on the interface, the **ResolveIpNetEntry2** function flushes the existing entry before resolving the IP address.

On output, when the call is successful, **ResolveIpNetEntry2** retrieves the other properties for the neighbor IP address and fills in the MIB_IPNET_ROW2 structure that the *Row* parameter points to. The **PhysicalAddress** and **PhysicalAddressLength** members in the MIB_IPNET_ROW2 structure are initialized to a valid physical address.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

SetIpNetEntry2

SetIpNetEntry2 function

Article • 03/03/2023

The **SetIpNetEntry2** function sets the physical address of an existing neighbor IP address entry on a local computer.

Syntax

```
C++

NETIOAPI_API SetIpNetEntry2(
  _In_ PMIB_IPNET_ROW2 Row
);
```

Parameters

- *Row* [in]
  A pointer to a MIB_IPNET_ROW2 structure entry for a neighbor IP address entry.

Return value

SetIpNetEntry2 return STATUS_SUCCESS if the function succeeds.

If the function fails, **SetIpNetEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned in the following situations. • A **NULL** pointer was passed in the *Row* parameter. • The **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to was not set to a valid unicast, anycast, or multicast IPv4 or IPv6 address. • The **PhysicalAddress** and **PhysicalAddressLength** members of the MIB_IPNET_ROW2 structure were not set to a valid physical address. • Both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPNET_ROW2 structure were unspecified. • A loopback address was passed in the **Address** member.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must initialize the following members of the **MIB_IPNET_ROW2** structure that the *Row* parameter points to.

- **Address**
  Set to a valid unicast, anycast, or multicast IPv4 or IPv6 address and family.

- **PhysicalAddress** and **PhysicalAddressLength**
  Set to a valid physical address.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

The **SetIpNetEntry2** function fails if the IP address that is passed in the **Address** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to is not an existing neighbor IP address on the interface that is specified.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Netioapi.h (include Netioapi.h)

FlushIpPathTable function

Article • 03/03/2023

The **FlushIpPathTable** function flushes the IP path table on a local computer.

Syntax

```c++
NETIOAPI_API FlushIpPathTable(
  _In_ ADDRESS_FAMILY Family
);
```

Parameters

- *Family* [in]
  The address family to flush.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function flushes the IP path table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function flushes the IP path table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function flushes the neighbor IP address table that contains both IPv4 and IPv6 entries.

Return value

FlushIpPathTable returns STATUS_SUCCESS if the function succeeds.

If the function fails, **FlushIpPathTable** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **FlushIpPathTable** function flushes or deletes the IP path entries on a local computer. Your driver can use the *Family* parameter to limit the IP path entries to delete to a particular IP address family. If IP path entries for both IPv4 and IPv6 should be deleted, your driver should set the *Family* parameter to AF_UNSPEC.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

GetIpPathEntry

GetIpPathTable

MIB_IPPATH_ROW

MIB_IPPATH_TABLE

GetIpPathEntry function

Article • 03/03/2023

The **GetIpPathEntry** function retrieves information for an IP path entry on a local computer.

Syntax

```
C++

NETIOAPI_API GetIpPathEntry(
  _Inout_ PMIB_IPPATH_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPPATH_ROW structure entry for an IP path entry. On successful return, this structure is updated with the properties for IP path entry.

Return value

GetIpPathEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpPathEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **si_family** member in the **Destination** member of the MIB_IPPATH_ROW structure that the *Row* parameter points to was not set to AF_INET or AF_INET6, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPPATH_ROW structure were unspecified. This error is also returned if the **si_family** member in the **Source** member of the MIB_IPPATH_ROW structure did not match the destination IP address family and the **si_family** for the source IP address was not specified as AF_UNSPEC.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPPATH_ROW structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Source** and **Destination** members of the MIB_IPPATH_ROW structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Source** and **Destination** members.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpPathEntry** function is used to retrieve a **MIB_IPPATH_ROW** structure entry.

On input, your driver must initialize the following members of the MIB_IPPATH_ROW structure that the *Row* parameter points to.

- **Destination**
  Set to a valid IPv4 or IPv6 address and family.

- **Source**
  Set the address family that is specified in the **Source** member to the destination IP address family that is specified in the **Destination** member, or to AF_UNSPEC.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetIpPathEntry** retrieves the other properties for the IP path entry and fills in the MIB_IPPATH_ROW structure that the *Row* parameter points to.

Your driver can call the **GetIpPathTable** function to enumerate the IP path entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

FlushIpPathTable

GetIpPathTable

MIB_IPPATH_ROW

MIB_IPPATH_TABLE

GetIpPathTable function

Article • 03/03/2023

The **GetIpPathEntry** function retrieves information for an IP path entry on a local computer.

Syntax

```C++
NETIOAPI_API GetIpPathTable(
  _In_  ADDRESS_FAMILY    Family,
  _Out_ PMIB_IPPATH_TABLE *Table
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function returns the IP path table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function returns the IP path table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function

returns the IP path table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a MIB_IPPATH_TABLE structure that contains a table of IP path entries on the local computer.

Return value

GetIpPathEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpPathEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No IP path entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpPathTable** function enumerates the IP path entries on a local computer and returns this information in a MIB_IPPATH_TABLE structure.

GetIpPathTable returns the IP path entries in a MIB_IPPATH_TABLE structure in the buffer that the *Table* parameter points to. The MIB_IPPATH_TABLE structure contains an IP path entry count and an array of MIB_IPPATH_ROW structures for each IP path entry. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_IPPATH_TABLE structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IPPATH_ROW array entry in the **Table** member of the MIB_IPPATH_TABLE structure. Padding for alignment might also be present between the MIB_IPPATH_ROW array entries. Any access to a MIB_IPPATH_ROW array entry should assume padding might exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

MIB_IPPATH_TABLE

CreateIpForwardEntry2 function

Article • 03/03/2023

The **CreateIpForwardEntry2** function creates a new IP route entry on a local computer.

Syntax

```
C++
```

```
NETIOAPI_API CreateIpForwardEntry2(
  _In_ const MIB_IPFORWARD_ROW2 *Row
);
```

Parameters

- *Row* [in]

  A pointer to a MIB_IPFORWARD_ROW2 structure entry for an IP route entry.

Return value

CreateIpForwardEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CreateIpForwardEntry2** returns one of the following error codes:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if one of the following situations occurs: - A **NULL** pointer is passed in the *Row* parameter. - The **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to was not specified. - The **NextHop** member of the MIB_IPFORWARD_ROW2 structure was not specified. - Both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPFORWARD_ROW2 structure were unspecified. - The **PreferredLifetime** member of the MIB_IPFORWARD_ROW2 structure is greater than the **ValidLifetime** member. - The **SitePrefixLength** member of the MIB_IPFORWARD_ROW2 structure is greater than the prefix length that is specified by the **DestinationPrefix** member. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that is pointed to by the *Row* parameter was not specified, the **NextHop** member of the MIB_IPFORWARD_ROW2 structure was not specified, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPFORWARD_ROW2 structure were unspecified. This error is also returned if the **PreferredLifetime** member that is specified in the MIB_IPFORWARD_ROW2 structure is greater than the **ValidLifetime** member, or if the **SitePrefixLength** in the MIB_IPFORWARD_ROW2 structure is greater than the prefix length that is specified in the **DestinationPrefix** member.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPNET_ROW2 structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if the interface that is specified does not support routes. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the address family in the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and AF_INET6 was specified for the address family in the **DestinationPrefix** member.
ERROR_OBJECT_ALREADY_EXISTS	The object already exists. This error is returned if the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to is a duplicate of an existing IP route entry on the interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPFORWARD_ROW2 structure.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **CreateIpForwardEntry2** function is used to add a new neighbor IP address entry on a local computer. Use the **InitializeIpForwardEntry** function to initialize the members of a **MIB_IPFORWARD_ROW2** structure entry with default values. A driver can then change the members in the MIB_IPFORWARD_ROW2 entry that it wants to modify and then call **CreateIpForwardEntry2**.

Your driver must initialize the following members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to:

- Set **DestinationPrefix** to a valid IPv4 or IPv6 address prefix.
- Set **NextHop** to a valid IPv4 or IPv6 address and family.
- Set **InterfaceLuid** or **InterfaceIndex** to the LUID or index value of the interface.

The **InterfaceLuid** and **InterfaceIndex** members are used in the order that is listed earlier. So if the **InterfaceLuid** is specified, this member is used to determine the interface to add the IP route entry on. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

The route metric offset that is specified in the **Metric** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to represents only part of the complete route metric. The complete metric is a combination of this route metric offset added to the interface metric that is specified in the **Metric** member of the MIB_IPINTERFACE_ROW structure of the associated interface. A driver can retrieve the interface metric by calling the GetIpInterfaceEntry function.

The **Age** and **Origin** members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to are ignored when the **CreateIpForwardEntry2** function is called. These members are set by the network stack and cannot be set by using the **CreateIpForwardEntry2** function.

The **CreateIpForwardEntry2** function fails if the **DestinationPrefix** and **NextHop** members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to are a duplicate of an existing IP route entry on the interface that is specified in the **InterfaceLuid** or **InterfaceIndex** members.

Requirements

Target platform	Universal

DeleteIpForwardEntry2 function

Article • 03/03/2023

The **DeleteIpForwardEntry2** function deletes an IP route entry on a local computer.

Syntax

```
C++

NETIOAPI_API DeleteIpForwardEntry2(
  _In_ const MIB_IPFORWARD_ROW2 *Row
);
```

Parameters

- *Row* [in]

  A pointer to a MIB_IPFORWARD_ROW2 structure entry for an IP route entry. On successful return, this entry is deleted.

Return value

DeleteIpForwardEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **DeleteIpForwardEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to was not specified, the **NextHop** member of the MIB_IPFORWARD_ROW2 structure was not specified, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPFORWARD_ROW2 structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to.

Return code	Description
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address was specified in the **Address** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and an IPv6 address was specified in the **Address** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **DeleteIpForwardEntry2** function is used to delete a **MIB_IPFORWARD_ROW2** structure entry.

On input, your driver must initialize the following members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to.

- **DestinationPrefix**
  Set to a valid IPv4 or IPv6 address prefix and family.

- **NextHop**
  Set to a valid IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **DeleteIpForwardEntry2** deletes the IP route entry.

The **DeleteIpForwardEntry2** function fails if the **DestinationPrefix** and **NextHop** members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to do not match an existing IP route entry on the interface that is specified in the **InterfaceLuid** or **InterfaceIndex** members.

Your driver can call the **GetIpForwardTable2** function to enumerate the IP route entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

GetBestRoute2 function

Article • 03/03/2023

The **GetBestRoute2** function retrieves the IP route entry on a local computer for the best route to the specified destination IP address.

Syntax

C++

```
NETIOAPI_API GetBestRoute2(
  _In_opt_       NET_LUID            *InterfaceLuid,
  _In_           NET_IFINDEX         InterfaceIndex,
  _In_opt_ const SOCKADDR_INET       *SourceAddress,
  _In_     const SOCKADDR_INET       *DestinationAddress,
  _In_           ULONG               AddressSortOptions,
  _Out_          PMIB_IPFORWARD_ROW2 BestRoute,
  _Out_          SOCKADDR_INET       *BestSourceAddress
);
```

Parameters

- *InterfaceLuid* [in, optional]
  The locally unique identifier (LUID) to specify the network interface that is associated with an IP route entry.

- *InterfaceIndex* [in]
  The local index value to specify the network interface that is associated with an IP route entry. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, so this value does not persistent.

- *SourceAddress* [in, optional]
  The source IP address. Your driver can omit this parameter and pass a **NULL** pointer.

- *DestinationAddress* [in]
  The destination IP address.

- *AddressSortOptions* [in]
  A set of options that affect how IP addresses are sorted. This parameter is currently not used.

- *BestRoute* [out]
  A pointer to the MIB_IPFORWARD_ROW2 structure for the best route from the source IP address to the destination IP address.

- *BestSourceAddress* [out]
  A pointer to the best source IP address.

Return value

GetBestRoute2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetBestRoute2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *DestinationAddress*, *BestSourceAddress*, or *BestRoute* parameters. This error is also returned if both *InterfaceLuid* and *InterfaceIndex* parameters were unspecified. This error is also returned if the *DestinationAddress* parameter does not specify an IPv4 or IPv6 address and family
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the network interface that the *InterfaceLuid* or *InterfaceIndex* parameter specifies could not be found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and an IPv4 address and family was specified in the *DestinationAddress* parameter, or if no IPv6 stack is located on the local computer and an IPv4 address and family was specified in the *DestinationAddress* parameter.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetBestRoute2** function is used to retrieve a MIB_IPFORWARD_ROW2 structure entry for the best route from a source IP address to a destination IP address.

On input, your driver must initialize the following parameters.

- *DestinationAddress*
  Set to a valid IPv4 or IPv6 address and family.

- *InterfaceLuid* or *InterfaceIndex*
  These parameters are used in the order that is listed earlier. So if *InterfaceLuid* is specified, this parameter is used to determine the interface. If no value was set for the *InterfaceLuid* member (the value of this parameter was set to zero), the *InterfaceIndex* parameter is next used to determine the interface.

In addition, on input, your driver can initialize the *SourceAddress* parameter to the preferred IPv4 or IPv6 address and family.

On output, when the call is successful, **GetBestRoute2** retrieves an MIB_IPFORWARD_ROW2 structure for the best route from the source IP address the destination IP address.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

SetIpForwardEntry2

GetIpForwardEntry2 function

Article • 03/03/2023

The **GetIpForwardEntry2** function retrieves information for an IP route entry on a local computer.

Syntax

```
C++
```

```
NETIOAPI_API GetIpForwardEntry2(
  _Inout_ PMIB_IPFORWARD_ROW2 Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPFORWARD_ROW2 structure entry for an IP route entry. On successful return, this structure is updated with the properties for the IP route entry.

Return value

GetIpForwardEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpForwardEntry2** returns one of the following error codes:

Return code	Description

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if one of the following situations occurs: - A **NULL** pointer is passed in the *Row* parameter. - The **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to was not specified. - The **NextHop** member of the MIB_IPFORWARD_ROW2 structure was not specified. - Both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPFORWARD_ROW2 structure were unspecified. - The **PreferredLifetime** member of the MIB_IPFORWARD_ROW2 structure is greater than the **ValidLifetime** member. - The **SitePrefixLength** member of the MIB_IPFORWARD_ROW2 structure is greater than the prefix length that is specified by the **DestinationPrefix** member.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the address family in the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to, or if no IPv6 stack is located on the local computer and AF_INET6 was specified for the address family in the **DestinationPrefix** member.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpForwardEntry2** function is used to retrieve a MIB_IPFORWARD_ROW2 structure entry.

On input, your driver must initialize the following members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to.

- **DestinationPrefix**
  Set to a valid IPv4 or IPv6 address prefix and family.

- **NextHop**
  Set to a valid IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, when the call is successful, **GetIpForwardEntry2** retrieves the other properties for the IP route entry and fills out the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to.

The route metric offset that is specified in the **Metric** member of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to represents only part of the complete route metric. The complete metric is a combination of this route metric added to the interface metric that is specified in the **Metric** member of the MIB_IPINTERFACE_ROW structure of the associated interface. A driver can retrieve the interface metric by calling the GetIpInterfaceEntry function.

Your driver can call the GetIpForwardTable2 function to enumerate the IP route entries on a local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

SetIpForwardEntry2

GetIpForwardTable2 function

Article • 03/03/2023

The **GetIpForwardTable2** function retrieves the IP route entries on a local computer.

Syntax

```
C++

NETIOAPI_API GetIpForwardTable2(
  _In_  ADDRESS_FAMILY        Family,
  _Out_ PMIB_IPFORWARD_TABLE2 *Table
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function returns the IP routing table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function returns the IP routing table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function returns the IP routing table that contains both IPv4 and IPv6 entries.

- *Table* [out]

  A pointer to a MIB_IPFORWARD_TABLE2 structure that contains a table of IP route entries on the local computer.

Return value

GetIpForwardTable2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpForwardTable2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Table* parameter or the *Family* parameter was not specified as AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	Insufficient memory resources are available to complete the operation.
STATUS_NOT_FOUND	No IP route entries, as specified in the *Family* parameter, were found.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv4 stack is located on the local computer and AF_INET was specified in the *Family* parameter, or if no IPv6 stack is located on the local computer and AF_INET6 was specified in the *Family* parameter. This error is also returned on versions of Windows where this function is not supported.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetIpForwardTable2** function enumerates the IP route entries on a local computer and returns this information in a MIB_IPFORWARD_TABLE2 structure.

The IP route entries are returned in a MIB_IPFORWARD_TABLE2 structure in the buffer that the *Table* parameter points to. The MIB_IPFORWARD_TABLE2 structure contains an IP route entry count and an array of MIB_IPFORWARD_ROW2 structures for each IP route entry. When these returned structures are no longer required, your driver should free the memory by calling FreeMibTable.

Your driver must initialize the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

Note that the returned MIB_IPFORWARD_TABLE2 structure that the *Table* parameter points to might contain padding for alignment between the **NumEntries** member and the first MIB_IPFORWARD_ROW2 array entry in the **Table** member of the MIB_IPFORWARD_TABLE2 structure. Padding for alignment might also be present between the MIB_IPFORWARD_ROW2 array entries. Any access to a MIB_IPFORWARD_ROW2 array entry should assume padding might exist.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

SetIpForwardEntry2

GetIpInterfaceEntry function

Article • 03/03/2023

The **GetIpInterfaceEntry** function retrieves IP information for the specified interface on a local computer.

Syntax

```c++
NETIOAPI_API GetIpInterfaceEntry(
  _Inout_ PMIB_IPINTERFACE_ROW Row
);
```

Parameters

- *Row* [in, out]
  A pointer to a MIB_IPINTERFACE_ROW structure that, on successful return, receives information for an interface on the local computer. On input, your driver must set the **InterfaceLuid** member or the **InterfaceIndex** member of the MIB_IPINTERFACE_ROW to the interface to retrieve information for.

Return value

GetIpInterfaceEntry returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetIpInterfaceEntry** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Row* parameter, the **Family** member of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to was not specified as AF_INET or AF_INET6, or the **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPINTERFACE_ROW structure were unspecified.
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to.

Return code	Description
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

On input, your driver must initialize the following members of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to.

- **Family**
  Set to either AF_INET or AF_INET6.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

On output, **GetIpInterfaceEntry** fills in the remaining members of the MIB_IPINTERFACE_ROW structure that the *Row* parameter points to.

Your driver must use the InitializeIpInterfaceEntry function to initialize the fields of a MIB_IPINTERFACE_ROW structure entry with default values. A driver can then change the fields in the MIB_IPINTERFACE_ROW entry that it wants to modify, and then call the SetIpInterfaceEntry function.

Unprivileged simultaneous access to multiple networks of different security requirements creates a security hole and enables an unprivileged driver to accidentally relay data between the two networks. A typical example is simultaneous access to a virtual private network (VPN) and the Internet. The Windows Server 2003 and Windows XP operating systems use a weak host model, where Remote Access Service (RAS) prevents such simultaneous access by increasing the route metric of all default routes over other interfaces. Therefore, all traffic is routed through the VPN interface, disrupting other network connectivity.

On Windows Vista and later versions of the Windows operating systems, by default, a strong host model is used. If a source IP address is specified in the route lookup by using the GetBestRoute2 function, the route lookup is restricted to the interface of the source IP address. The route metric modification by RAS has no effect because the list of potential routes does not even have the route for the VPN interface, which enables traffic to the Internet. Your driver can use the **DisableDefaultRoutes** member of the MIB_IPINTERFACE_ROW to disable using the default route on an interface. VPN clients can use this member as a security measure to restrict split tunneling when split tunneling is not required by the VPN client. A VPN client can call the SetIpInterfaceEntry function to set the **DisableDefaultRoutes** member to **TRUE** when it is required. A VPN client can query the current state of the **DisableDefaultRoutes** member by calling the **GetIpInterfaceEntry** function.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib

SetIpInterfaceEntry

InitializeIpForwardEntry function

Article • 03/03/2023

The **InitializeIpForwardEntry** function initializes a MIB_IPFORWARD_ROW2 structure with default values for an IP route entry on a local computer.

Syntax

```c++
VOID NETIOAPI_API_ InitializeIpForwardEntry(
  _Out_ PMIB_IPFORWARD_ROW2 Row
);
```

Parameters

- *Row* [out]
  On entry, a pointer to a MIB_IPFORWARD_ROW2 structure entry for an IP route entry.

  On return, the MIB_IPFORWARD_ROW2 structure that this parameter points to is initialized with default values for an IP route entry.

Return value

None

Remarks

Your driver must use the **InitializeIpForwardEntry** function to initialize the members of a MIB_IPFORWARD_ROW2 structure entry with default values for an IP route entry for later use with the CreateIpForwardEntry2 function.

On input, your driver must pass **InitializeIpForwardEntry** a new MIB_IPFORWARD_ROW2 structure to initialize.

On output, the members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to are initialized as follows.

- **ValidLifetime** and **PreferredLifetime**
  Set to an infinite value,

- **Loopback**, **AutoconfigureAddress**, **Publish**, and **Immortal**
  Set to **TRUE**.

- **SitePrefixLength**, **Metric**, and **Protocol**
  Set to illegal values.

- All other members
  Set to zero.

After a driver calls **InitializeIpForwardEntry**, the driver can then change the members in the MIB_IPFORWARD_ROW2 entry that it wants to modify, and then call the **CreateIpForwardEntry2** to add the new IP route entry to the local computer.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

SetIpForwardEntry2

SetIpForwardEntry2 function

Article • 03/03/2023

The **SetIpForwardEntry2** function sets the properties of an IP route entry on a local computer.

Syntax

```
C++

NETIOAPI_API SetIpForwardEntry2(
  _In_ const MIB_IPFORWARD_ROW2 *Route
);
```

Parameters

- *Route* [in]
  A pointer to a MIB_IPFORWARD_ROW2 structure entry for an IP route entry. Your driver must set the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure to a valid IP destination prefix and family, set the **NextHop** member of MIB_IPFORWARD_ROW2 to a valid IP address and family, and specify the **InterfaceLuid** member or the **InterfaceIndex** member of MIB_IPFORWARD_ROW2.

Return value

SetIpForwardEntry2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **SetIpForwardEntry2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Route* parameter, the **DestinationPrefix** member of the MIB_IPFORWARD_ROW2 structure that the *Route* parameter points to was not specified, the **NextHop** member of the MIB_IPFORWARD_ROW2 structure was not specified, or both **InterfaceLuid** and **InterfaceIndex** members of the MIB_IPFORWARD_ROW2 structure were unspecified.

Return code	Description
STATUS_NOT_FOUND	The specified interface could not be found. This error is returned if the function cannot find the network interface that is specified by the **InterfaceLuid** or **InterfaceIndex** member of the MIB_IPFORWARD_ROW2 structure that the *Route* parameter points to.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **SetIpForwardEntry2** function is used to set the properties for an existing IP route entry on a local computer.

Your driver must initialize the following members of the **MIB_IPFORWARD_ROW2** structure that the *Row* parameter points to.

- **DestinationPrefix**
  Set to a valid IPv4 or IPv6 address prefix and family.

- **NextHop**
  Set to a valid IPv4 or IPv6 address and family.

- **InterfaceLuid** or **InterfaceIndex**
  These members are used in the order that is listed earlier. So if **InterfaceLuid** is specified, this member is used to determine the interface. If no value was set for the **InterfaceLuid** member (the value of this member was set to zero), the **InterfaceIndex** member is next used to determine the interface.

The route metric offset that is specified in the **Metric** member of the MIB_IPFORWARD_ROW2 structure that *Route* parameter points to represents only part of the complete route metric. The complete metric is a combination of this route metric offset added to the interface metric that is specified in the **Metric** member of the **MIB_IPINTERFACE_ROW** structure of the associated interface. A driver can retrieve the interface metric by calling the **GetIpInterfaceEntry** function.

SetIpForwardEntry2 ignores the **Age** and **Origin** members of the MIB_IPFORWARD_ROW2 structure that the *Row* parameter points to. These members are set by the network stack and cannot be changed by using the **SetIpForwardEntry2** function.

The **SetIpForwardEntry2** function fails if the **DestinationPrefix** and **NextHop** members of the MIB_IPFORWARD_ROW2 structure that the *Route* parameter points to do not match an an IP route entry on the specified interface.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

FreeMibTable function

Article • 03/03/2023

The **FreeMibTable** function frees the buffer that is allocated by the functions that return tables of network interfaces, addresses, and routes (for example, **GetIfTable2** and **GetAnycastIpAddressTable**).

Syntax

C++

```
VOID NETIOAPI_API_ FreeMibTable(
  _In_ PVOID Memory
);
```

Parameters

- *Memory* [in]

  A pointer to the buffer to free.

Return value

None

Remarks

The **FreeMibTable** function is used to free the internal buffers that various functions use to retrieve tables of interfaces, addresses, and routes. When these tables are no longer needed, your driver should call **FreeMibTable** to release the memory that these tables use.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

MIB_NOTIFICATION_TYPE enumeration

Article • 03/03/2023

The MIB_NOTIFICATION_TYPE enumeration type defines the notification type that is passed to a callback function when a notification occurs.

Syntax

```C++
typedef enum _MIB_NOTIFICATION_TYPE {
  MibParameterNotification  = 0,
  MibAddInstance            = 1,
  MibDeleteInstance         = 2,
  MibInitialNotification    = 3
} MIB_NOTIFICATION_TYPE, *PMIB_NOTIFICATION_TYPE;
```

Constants

- **MibParameterNotification**
  A parameter was changed.

- **MibAddInstance**
  A new MIB instance was added.

- **MibDeleteInstance**
  An existing MIB instance was deleted.

- **MibInitialNotification**
  A notification that is invoked immediately after registration for change notification completes. This initial notification does not indicate that a change occurred to a MIB instance. The purpose of this initial notification type is to provide confirmation that the callback function is properly registered.

Remarks

The MIB_NOTIFICATION_TYPE enumerated type is used with the callback function that is specified in the *Callback* parameter of one of the IP Helper **Notify*Xxx*** functions to specify the notification type.

On Windows Vista and later versions of the Windows operating systems, new functions are provided to register the driver to be notified when an IPv6 or IPv4 interface changes, an IPv6 or IPv4 unicast address changes, or an IPv6 or IPv4 route changes. These registration functions require that a callback function be passed that is called when a change occurs. One of the parameters that is passed to the callback function when a notification occurs is a parameter that contains a MIB_NOTIFICATION_TYPE value that indicates the notification type.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

IP_ADDRESS_PREFIX structure

Article • 03/03/2023

The IP_ADDRESS_PREFIX structure stores an IP address prefix.

Syntax

```c++
typedef struct _IP_ADDRESS_PREFIX {
  SOCKADDR_INET Prefix;
  UINT8         PrefixLength;
} IP_ADDRESS_PREFIX, *PIP_ADDRESS_PREFIX;
```

Members

- **Prefix**
  The prefix or network part of the address represented as an IP address.

- **PrefixLength**
  The length, in bits, of the prefix or network part of the IP address. For a unicast IPv4 address, any value that is greater than 32 is an illegal value. For a unicast IPv6 address, any value that is greater than 128 is an illegal value. A value of 255 is typically used to represent an illegal value.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

MIB_ANYCASTIPADDRESS_ROW structure

Article • 03/03/2023

The MIB_ANYCASTIPADDRESS_ROW structure stores information about an anycast IP address.

Syntax

```c++
typedef struct _MIB_ANYCASTIPADDRESS_ROW {
  SOCKADDR_INET Address;
  NET_LUID      InterfaceLuid;
  NET_IFINDEX   InterfaceIndex;
  SCOPE_ID      ScopeId;
} MIB_ANYCASTIPADDRESS_ROW, *PMIB_ANYCASTIPADDRESS_ROW;
```

Members

- **Address**
  The anycast IP address. This member can be an IPv6 address or an IPv4 address.

- **InterfaceLuid**
  The locally unique identifier (LUID) for the network interface that is associated with this IP address.

- **InterfaceIndex**
  The local index value for the network interface that is associated with this IP address. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **ScopeId**
  The scope ID of the anycast IP address. This member is applicable only to an IPv6 address. Your driver cannot set this member. This member is automatically determined by the interface that the address was added on.

Remarks

The GetAnycastIpAddressTable function enumerates the anycast IP addresses on a local computer and returns this information in a MIB_ANYCASTIPADDRESS_TABLE structure.

The MIB_ANYCASTIPADDRESS_TABLE structure might contain padding for alignment between the **NumEntries** member and the first MIB_ANYCASTIPADDRESS_ROW array entry in the **Table** member. Padding for alignment might also be present between the MIB_ANYCASTIPADDRESS_ROW array entries in the **Table** member. Any access to a MIB_ANYCASTIPADDRESS_ROW array entry should assume padding might exist.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

MIB_ANYCASTIPADDRESS_TABLE

MIB_ANYCASTIPADDRESS_TABLE structure

Article • 03/03/2023

The MIB_ANYCASTIPADDRESS_TABLE structure contains a table of anycast IP address entries.

Syntax

```
C++

typedef struct _MIB_ANYCASTIPADDRESS_TABLE {
  ULONG                       NumEntries;
  MIB_ANYCASTIPADDRESS_ROW Table[ANY_SIZE];
} MIB_ANYCASTIPADDRESS_TABLE, *PMIB_ANYCASTIPADDRESS_TABLE;
```

Members

- **NumEntries**
  A value that specifies the number of anycast IP address entries in the array.

- **Table**
  An array of MIB_ANYCASTIPADDRESS_ROW structures that contain anycast IP address entries.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)

  ULONG64                    OutBroadcastOctets;
  ULONG64                    OutQLen;
} MIB_IF_ROW2, *PMIB_IF_ROW2;
```

Members

- **InterfaceLuid**
  The locally unique identifier (LUID) for the network interface.

- **InterfaceIndex**
  The index that identifies the network interface. This index value might change when a network adapter is disabled and then enabled, and should not be considered persistent.

- **InterfaceGuid**
  The GUID for the network interface.

- **Alias**
  A NULL-terminated Unicode string that contains the alias name of the network interface.

- **Description**
  A NULL-terminated Unicode string that contains a description of the network interface.

- **PhysicalAddressLength**
  The length, in bytes, of the physical hardware address that the PhysicalAddress member specifies.

- **PhysicalAddress**
  The physical hardware address of the adapter for this network interface.

- **PermanentPhysicalAddress**
  The permanent physical hardware address of the adapter for this network interface.

- **Mtu**
  The maximum transmission unit (MTU) size, in bytes, for this network interface.

- **Type**
  The interface type as defined by the Internet Assigned Names Authority (IANA). For more information, see IANAifType-MIB DEFINITIONS. Possible values for the interface type are listed in the Ipifcons.h header file.

  The following table lists common values for the interface type, although many other values are possible.

Value	Meaning
IF_TYPE_OTHER 1	Some other type of network interface
IF_TYPE_ETHERNET_CSMACD 6	An Ethernet network interface
IF_TYPE_ISO88025_TOKENRING 9	A token ring network interface
IF_TYPE_PPP 23	A PPP network interface
IF_TYPE_SOFTWARE_LOOPBACK 24	A software loopback network interface
IF_TYPE_ATM 37	An ATM network interface
IF_TYPE_IEEE80211 71	An IEEE 802.11 wireless network interface
IF_TYPE_TUNNEL 131	A tunnel type encapsulation network interface
IF_TYPE_IEEE1394 144	An IEEE 1394 (Firewire) high performance serial bus network interface

- **TunnelType**
  If the Type member is IF_TYPE_TUNNEL, a **TUNNEL_TYPE** type that defines the

encapsulation method that a tunnel uses.

- **MediaType**
  The NDIS media type for the interface. This member can be one of the following values from the NDIS_MEDIUM enumeration type that is defined in the Ntddndis.h header file.

Value	Meaning
NdisMedium802_3 0	An Ethernet (802.3) network.
NdisMedium802_5 1	A Token Ring (802.5) network.
NdisMediumFddi 2	A Fiber Distributed Data Interface (FDDI) network.
NdisMediumWan 3	A wide area network (WAN). This type covers various forms of point-to-point and WAN NICs and variant address/header formats that must be negotiated between the protocol driver and the underlying driver after the binding is established.
NdisMediumLocalTalk 4	A LocalTalk network.
NdisMediumDix 5	An Ethernet network for which the drivers use the DIX Ethernet header format.
NdisMediumArcnetRaw 6	An ARCNET network.
NdisMediumArcnet878_2 7	An ARCNET (878.2) network.
NdisMediumAtm 8	An ATM network. Connection-oriented client protocol drivers can bind themselves to an underlying miniport driver that returns this value. Otherwise, legacy protocol drivers bind themselves to the system-supplied LanE intermediate driver, which reports its medium type as either **NdisMedium802_3** or NdisMedium802_5, depending on how the network administrator configures the LanE driver.

Value	Meaning
NdisMediumWirelessWan 9	A wireless network. NDIS 5. x miniport drivers that support wireless LAN (WLAN) or wireless WAN (WWAN) packets declare their medium as **NdisMedium802_3** and emulate Ethernet to higher-level NDIS drivers. Note This media type is not available for use on Windows Vista or later versions of Windows.
NdisMediumIrda 10	An infrared (IrDA) network.
NdisMediumBpc 11	A broadcast computer network.
NdisMediumCoWan 12	A wide area network in a connection-oriented environment.
NdisMedium1394 13	An IEEE 1394 (fire wire) network.
NdisMediumInfiniBand 14	An InfiniBand network.
NdisMediumTunnel 15	A tunnel network.
NdisMediumNative802_11 16	A native IEEE 802.11 network.
NdisMediumLoopback 17	An NDIS loopback network.

- **PhysicalMediumType**
  The NDIS physical medium type. This member can be one of the following values from the NDIS_PHYSICAL_MEDIUM enumeration type that is defined in the Ntddndis.h header file.

Value	Meaning

Value	Meaning
NdisPhysicalMediumUnspecified 0	The physical medium is none of the following values. For example, a one-way satellite feed is an unspecified physical medium.
NdisPhysicalMediumWirelessLan 1	Packets are transferred over a wireless LAN network through a miniport driver that complies with the 802.11 interface.
NdisPhysicalMediumCableModem 2	Packets are transferred over a DOCSIS-based cable network.
NdisPhysicalMediumPhoneLine 3	Packets are transferred over standard telephone lines. This type includes HomePNA media.
NdisPhysicalMediumPowerLine 4	Packets are transferred over wiring that is connected to a power distribution system.
NdisPhysicalMediumDSL 5	Packets are transferred over a Digital Subscriber Line (DSL) network. This type includes ADSL, UADSL (G.Lite), and SDSL.
NdisPhysicalMediumFibreChannel 6	Packets are transferred over a Fibre Channel interconnect.
NdisPhysicalMedium1394 7	Packets are transferred over an IEEE 1394 bus.
NdisPhysicalMediumWirelessWan 8	Packets are transferred over a Wireless WAN link. This type includes CDPD, CDMA and GPRS.
NdisPhysicalMediumNative802_11 9	Packets are transferred over a wireless LAN network through a miniport driver that complies with the Native 802.11 interface. Note The Native 802.11 interface is supported in NDIS 6.0 and later versions.
NdisPhysicalMediumBluetooth 10	Packets are transferred over a Bluetooth network. Bluetooth is a short-range wireless technology that uses the 2.4 GHz spectrum.
NdisPhysicalMediumInfiniband 11	Packets are transferred over an InfiniBand interconnect.

Value	Meaning
NdisPhysicalMediumUWB 13	Packets are transferred over an ultra wide band network.
NdisPhysicalMedium802_3 14	Packets are transferred over an Ethernet (802.3) network.
NdisPhysicalMedium802_5 15	Packets are transferred over a Token Ring (802.5) network.
NdisPhysicalMediumIrda 16	Packets are transferred over an infrared (IrDA) network.
NdisPhysicalMediumWiredWAN 17	Packets are transferred over a wired WAN network.
NdisPhysicalMediumWiredCoWan 18	Packets are transferred over a wide area network in a connection-oriented environment.
NdisPhysicalMediumOther 19	Packets are transferred over a network that is not described by other possible values.

- AccessType
  A NET_IF_ACCESS_TYPE NDIS network interface access type.

- DirectionType
  A NET_IF_DIRECTION_TYPE NDIS network interface direction type.

- InterfaceAndOperStatusFlags
  A set of the following flags that provide information about the interface. These flags are combined with a bitwise OR operation. If none of the flags applies, this member is set to zero.

  - HardwareInterface
    The network interface is for hardware.

  - FilterInterface
    The network interface is for a filter module.

  - ConnectorPresent
    A connector is present on the network interface. This value is set if there is a physical network adapter.

  - NotAuthenticated
    The default port for the network interface is not authenticated. If a network interface is not authenticated by the target, the network interface is not in an operational mode. Although this situation applies to both wired and wireless network connections, authentication is more common for wireless network connections.

  - NotMediaConnected
    The network interface is not in a media-connected state. If a network cable is unplugged for a wired network, this value is set. For a wireless network, this value is set for the network adapter that is not connected to a network.

  - Paused
    The network stack for the network interface is in the paused or pausing state. This value does not mean that the computer is in a hibernated state.

  - LowPower
    The network interface is in a low power state.

  - EndPointInterface
    The network interface is an endpoint device and not a true network interface that connects to a network. This value can be set by devices, such as smartphones, that use networking infrastructure to communicate to the computer but do not provide connectivity to an external network. These types of devices must set this flag.

- OperStatus
  A IF_OPER_STATUS NDIS network interface operational status type.

- AdminStatus
  The NET_IF_ADMIN_STATUS administrative status type.

- MediaConnectState
  The NET_IF_MEDIA_CONNECT_STATE connection state type.

- NetworkGuid
  The GUID that is associated with the network that the interface belongs to.

- ConnectionType
  A NET_IF_CONNECTION_TYPE NDIS network interface connection type.

- TransmitLinkSpeed
  The speed, in bits per second, of the transmit link.

- **ReceiveLinkSpeed**
  The speed, in bits per second, of the receive link.

- **InOctets**
  The number of octets of data that are received without errors through this interface. This value includes octets in unicast, broadcast, and multicast packets.

- **InUcastPkts**
  The number of unicast packets that are received without errors through this interface.

- **InNUcastPkts**
  The number of non-unicast packets that are received without errors through this interface. This value includes broadcast and multicast packets.

- **InDiscards**
  The number of incoming packets that were discarded even though they did not have errors.

- **InErrors**
  The number of incoming packets that were discarded because of errors.

- **InUnknownProtos**
  The number of incoming packets that were discarded because the protocol was unknown.

- **InUcastOctets**
  The number of octets of data that are received without errors in unicast packets through this interface.

- **InMulticastOctets**
  The number of octets of data that are received without errors in multicast packets through this interface.

- **InBroadcastOctets**
  The number of octets of data that are received without errors in broadcast packets through this interface.

- **OutOctets**
  The number of octets of data that are transmitted without errors through this interface. This value includes octets in unicast, broadcast, and multicast packets.

- **OutUcastPkts**
  The number of unicast packets that are transmitted without errors through this interface.

- OutNUcastPkts
  The number of non-unicast packets that are transmitted without errors through this interface. This value includes broadcast and multicast packets.

- OutDiscards
  The number of outgoing packets that were discarded even though they did not have errors.

- OutErrors
  The number of outgoing packets that were discarded because of errors.

- OutUcastOctets
  The number of octets of data that are transmitted without errors in unicast packets through this interface.

- OutMulticastOctets
  The number of octets of data that are transmitted without errors in multicast packets through this interface.

- OutBroadcastOctets
  The number of octets of data that are transmitted without errors in broadcast packets through this interface.

- OutQLen
  The transmit queue length. This field is not currently used.

Remarks

The values for the Type field are defined in the Ipifcons.h header file. Only the possible values that are listed in the description of the Type member are currently supported.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IF_TABLE2 structure

Article • 03/03/2023

The MIB_IF_TABLE2 structure contains a table of logical and physical interface entries.

Syntax

C++

```
typedef struct _MIB_IF_TABLE2 {
  ULONG       NumEntries;
  MIB_IF_ROW2 Table[ANY_SIZE];
} MIB_IF_TABLE2, *PMIB_IF_TABLE2;
```

Members

- **NumEntries**

  The number of interface entries in the array.

- **Table**

  An array of MIB_IF_ROW2 structures that contain interface entries.

Remarks

The GetIfTable2 and GetIfTable2Ex functions enumerate the logical and physical interfaces on a local computer and return this information in a MIB_IF_TABLE2 structure.

The MIB_IF_TABLE2 structure might contain padding for alignment between the **NumEntries** member and the first MIB_IF_ROW2 array entry in the **Table** member. Padding for alignment might also be present between the MIB_IF_ROW2 array entries in the **Table** member. Any access to a MIB_IF_ROW2 array entry should assume padding might exist.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IFSTACK_ROW structure

Article • 03/03/2023

The MIB_IFSTACK_ROW structure represents the relationship between two network interfaces.

Syntax

```
C++

typedef struct _MIB_IFSTACK_ROW {
  NET_IFINDEX HigherLayerInterfaceIndex;
  NET_IFINDEX LowerLayerInterfaceIndex;
} MIB_IFSTACK_ROW, *PMIB_IFSTACK_ROW;
```

Members

- **HigherLayerInterfaceIndex**
  The network interface index for the interface that is higher in the interface stack table.

- **LowerLayerInterfaceIndex**
  The network interface index for the interface that is lower in the interface stack table.

Remarks

The relationship between the interfaces in the interface stack is that the interface with the index in the **HigherLayerInterfaceIndex** member is immediately above the interface with the index in the **LowerLayerInterfaceIndex** member.

MIB_INVERTEDIFSTACK_TABLE

MIB_INVERTEDIFSTACK_TABLE structure

Article • 03/03/2023

The MIB_INVERTEDIFSTACK_TABLE structure contains a table of inverted network interface stack row entries. This table specifies the relationship of the network interfaces on an interface stack in reverse order.

Syntax

C++

```
typedef struct _MIB_INVERTEDIFSTACK_TABLE {
  ULONG                   NumEntries;
  MIB_INVERTEDIFSTACK_ROW Table[ANY_SIZE];
} MIB_INVERTEDIFSTACK_TABLE, *PMIB_INVERTEDIFSTACK_TABLE;
```

Members

- **NumEntries**

  The number of inverted interface stack row entries in the array.

- **Table**

  An array of **MIB_INVERTEDIFSTACK_ROW** structures that contain inverted interface stack row entries.

Remarks

The relationship between the interfaces in the interface stack is that the interface with the index in the **HigherLayerInterfaceIndex** member of the MIB_INVERTEDIFSTACK_ROW structure is immediately above the interface with the index in the **LowerLayerInterfaceIndex** member of the MIB_INVERTEDIFSTACK_ROW structure.

The **GetInvertedIfStackTable** function enumerates the inverted network interface stack row entries on a local computer and returns this information in a MIB_INVERTEDIFSTACK_TABLE structure.

The MIB_INVERTEDIFSTACK_TABLE structure might contain padding for alignment between the **NumEntries** member and the first **MIB_INVERTEDIFSTACK_ROW** array entry in the **Table** member. Padding for alignment might also be present between the

MIB_INVERTEDIFSTACK_ROW array entries in the **Table** member. Any access to a MIB_INVERTEDIFSTACK_ROW array entry should assume padding might exist.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IPFORWARD_ROW2 structure

Article • 03/03/2023

The MIB_IPFORWARD_ROW2 structure stores information about an IP route entry.

Syntax

```c++
typedef struct _MIB_IPFORWARD_ROW2 {
  NET_LUID          InterfaceLuid;
  NET_IFINDEX       InterfaceIndex;
  IP_ADDRESS_PREFIX DestinationPrefix;
  SOCKADDR_INET     NextHop;
  UCHAR             SitePrefixLength;
  ULONG             ValidLifetime;
  ULONG             PreferredLifetime;
  ULONG             Metric;
  NL_ROUTE_PROTOCOL Protocol;
  BOOLEAN           Loopback;
  BOOLEAN           AutoconfigureAddress;
  BOOLEAN           Publish;
  BOOLEAN           Immortal;
  ULONG             Age;
  NL_ROUTE_ORIGIN   Origin;
} MIB_IPFORWARD_ROW2, *PMIB_IPFORWARD_ROW2;
```

Members

- **InterfaceLuid**

  The locally unique identifier (LUID) for the network interface that is associated with this IP route entry.

- **InterfaceIndex**

  The local index value for the network interface that is associated with this IP route entry. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **DestinationPrefix**

  The IP address prefix for the destination IP address for this route.

- **NextHop**

  For a remote route, the IP address of the next system or gateway that is along the route. If the route is to a local loopback address or an IP address on the local link, the next hop is unspecified (all zeros). For a local loopback route, this member should be an IPv4 address of 0.0.0.0 for an IPv4 route entry or an IPv6 address address of 0::0 for an IPv6 route entry.

- **SitePrefixLength**
  The length, in bits, of the site prefix or network part of the IP address for this route. For an IPv4 route entry, any value that is greater than 32 is an illegal value. For an IPv6 route entry, any value that is greater than 128 is an illegal value. A value of 255 is typically used to represent an illegal value.

- **ValidLifetime**
  The maximum time, in seconds, that the IP route entry is valid. A value of 0xffffffff is considered to be infinite.

- **PreferredLifetime**
  The preferred time, in seconds, that the IP route entry is valid. A value of 0xffffffff is considered to be infinite.

- **Metric**
  The route metric offset value for this IP route entry. Note the actual route metric that is used to compute the route preference is the interface metric that is specified in the **Metric** member of the MIB_IPINTERFACE_ROW structure added to the route metric offset that is specified in this **Metric** member. The semantics of this metric are determined by the routing protocol that is specified in the **Protocol** member. If this metric is not used, its value should be set to -1. This value is documented in RFC 4292. For more information, see IP Forwarding Table MIB.

- **Protocol**
  The NL_ROUTE_PROTOCOL routing mechanism type that this IP route was added with.

- **Loopback**
  A value that specifies if the route is a loopback route (the gateway is on the local host).

- **AutoconfigureAddress**
  A value that specifies if the IP address is autoconfigured.

- **Publish**
  A value that specifies if the route is published.

- **Immortal**
  A value that specifies if the route is immortal.

- **Age**
  The number of seconds since the route was added or modified in the network routing table.

- **Origin**
  A NL_ROUTE_ORIGIN IP route origin type.

Remarks

The GetIpForwardTable2 function enumerates the IP route entries on a local computer and returns this information in a MIB_IPFORWARD_TABLE2 structure as an array of MIB_IPFORWARD_ROW2 entries.

The **GetIpForwardEntry2** function retrieves a single IP route entry and returns this information in a MIB_IPFORWARD_ROW2 structure.

An entry with the **Prefix** and the **PrefixLength** members of IP_ADDRESS_PREFIX set to zero in the **DestinationPrefix** member in the MIB_IPFORWARD_ROW2 structure is considered a default route. The MIB_IPFORWARD_TABLE2 might contain multiple MIB_IPFORWARD_ROW2 entries with the **Prefix** and the **PrefixLength** members of the IP_ADDRESS_PREFIX set to zero in the **DestinationPrefix** member when there are multiple network adapters installed.

The **Metric** member of a MIB_IPFORWARD_ROW2 entry is a value that is assigned to an IP route for a particular network interface that identifies the cost that is associated with using that route. For example, the metric can be valued in terms of link speed, hop count, or time delay. Automatic metric is a feature on Windows XP and later versions of the Windows operating systems that automatically configures the metric for the local routes that are based on link speed. By default, the automatic metric feature is enabled (the **UseAutomaticMetric** member of the MIB_IPINTERFACE_ROW structure is set to **TRUE**) on Windows XP and later. You can also manually configure this feature to assign a specific metric to an IP route.

The route metric that is specified in the **Metric** member of the MIB_IPFORWARD_ROW2 structure represents only the route metric offset. The complete metric is a combination of this route metric offset added to the interface metric that is specified in the **Metric** member of the MIB_IPINTERFACE_ROW structure of the associated interface. A driver can retrieve the interface metric by calling the GetIpInterfaceEntry function.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

  BOOLEAN                        DisableDefaultRoutes;
} MIB_IPINTERFACE_ROW, *PMIB_IPINTERFACE_ROW;
```

Members

- **Family**
  The address family. Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for this member are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported:

  - AF_INET
    The IPv4 address family.
  - AF_INET6
    The IPv6 address family.
  - AF_UNSPEC
    The address family is unspecified.

- **InterfaceLuid**
  The locally unique identifier (LUID) for the network interface.

- **InterfaceIndex**
  The local index value for the network interface. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **MaxReassemblySize**
  The maximum reassembly size, in bytes, of a fragmented IP packet. This member is currently set to zero and reserved for future use.

- **InterfaceIdentifier**
  Reserved for future use. This member is currently set to zero.

- **MinRouterAdvertisementInterval**
  The minimum router advertisement interval, in milliseconds, on this IP interface. This member defaults to 200 for IPv6. This member is applicable only if the **AdvertisingEnabled** member is set to **TRUE**.

- MaxRouterAdvertisementInterval

  The maximum router advertisement interval, in milliseconds, on this IP interface. This member defaults to 600 for IPv6. This member is applicable only if the **AdvertisingEnabled** member is set to **TRUE**.

- AdvertisingEnabled

  A value that indicates if router advertising is enabled on this IP interface. The default for IPv6 is that router advertisement is enabled only if the interface is configured to act as a router. The default for IPv4 is that router advertisement is disabled.

- ForwardingEnabled

  A value that indicates if IP forwarding is enabled on this IP interface.

- WeakHostSend

  A value that indicates if weak host send mode is enabled on this IP interface.

- WeakHostReceive

  A value that indicates if weak host receive mode is enabled on this IP interface.

- UseAutomaticMetric

  A value that indicates if the IP interface uses automatic metric.

- UseNeighborUnreachabilityDetection

  A value that indicates if neighbor unreachability detection is enabled on this IP interface.

- ManagedAddressConfigurationSupported

  A value that indicates if the IP interface supports managed address configuration by using DHCP.

- OtherStatefulConfigurationSupported

  A value that indicates if the IP interface supports other stateful configuration (for example, route configuration).

- AdvertiseDefaultRoute

  A value that indicates if the IP interface advertises the default route. This member is applicable only if the **AdvertisingEnabled** member is set to **TRUE**.

- RouterDiscoveryBehavior

  An NL_ROUTER_DISCOVERY_BEHAVIOR router discovery behavior type.

- DadTransmits

  The number of consecutive messages that are sent while the driver performs duplicate address detection on a tentative IP unicast address. A value of zero indicates that duplicate address detection is not performed on tentative IP addresses. A value of one indicates a single transmission with no follow up retransmissions. For IPv4, the default value for this member is 3. For IPv6, the default value for this member is 1. For IPv6, these messages are sent as IPv6 Neighbor Solicitation (NS) requests. This member is defined as DupAddrDetectTransmits in RFC 2462. For more information, see IPv6 "Stateless Address Autoconfiguration" ↗.

- **BaseReachableTime**
  The base for random reachable time, in milliseconds. The member is described in RFC 2461. For more information, see "Neighbor Discovery for IP Version 6 (IPv6)" ↗.

- **RetransmitTime**
  The IPv6 Neighbor Solicitation (NS) time-out, in milliseconds. The member is described in RFC 2461. For more information, see "Neighbor Discovery for IP Version 6 (IPv6)" ↗.

- **PathMtuDiscoveryTimeout**
  The path MTU discovery time-out, in milliseconds.

- **LinkLocalAddressBehavior**
  A **NL_LINK_LOCAL_ADDRESS_BEHAVIOR** link local address behavior type.

- **LinkLocalAddressTimeout**
  The link local IP address time-out, in milliseconds.

- **ZoneIndices**
  An array that specifies the zone part of scope IDs.

- **SitePrefixLength**
  The site prefix length, in bits, of the IP interface address. The length, in bits, of the site prefix or network part of the IP interface address. For an IPv4 address, any value that is greater than 32 is an illegal value. For an IPv6 address, any value that is greater than 128 is an illegal value. A value of 255 is typically used to represent an illegal value.

- **Metric**
  The interface metric. Note that the actual route metric that is used to compute the route preference is the summation of the route metric offset that is specified in the **Metric** member of the **MIB_IPFORWARD_ROW2** structure and the interface metric that is specified in this member.

- **NlMtu**
  The network layer MTU size, in bytes.

- **Connected**
  A value that indicates if the interface is connected to a network access point.

- **SupportsWakeUpPatterns**
  A value that specifies if the network interface supports Wake on LAN.

- **SupportsNeighborDiscovery**
  A value that specifies if the IP interface support neighbor discovery.

- **SupportsRouterDiscovery**
  A value that specifies if the IP interface support neighbor discovery.

- **ReachableTime**
  The base for random reachable time, in milliseconds. The member is described in RFC 2461. For more information, see Neighbor Discovery for IP Version 6 (IPv6) .

- **TransmitOffload**
  A set of flags that indicate the transmit offload capabilities for the IP interface. The NL_INTERFACE_OFFLOAD_ROD structure is defined in the Nldef.h header file.

- **ReceiveOffload**
  A set of flags that indicate the receive offload capabilities for the IP interface. The NL_INTERFACE_OFFLOAD_ROD structure is defined in the Nldef.h header file.

- **DisableDefaultRoutes**
  A value that indicates if using default route on the interface should be disabled. VPN clients can use this member to restrict split tunneling.

Remarks

The **Family**, **InterfaceLuid**, and **InterfaceIndex** members uniquely identify a MIB_IPINTERFACE_ROW entry.

When a unicast packet arrives at a host, IP must determine whether the packet is locally destined (its destination matches an address that is assigned to an interface of the host). IP implementations that follow a weak host model accept any locally destined packet, regardless of the interface that the packet was received on. IP implementations that follow the strong host model accept only locally destined packets if the destination address in the packet matches an address that is assigned to the interface that the packet was received on. The weak host model provides better network connectivity. However, it also makes hosts susceptible to multihome-based network attacks.

The current IPv4 implementation in the Windows Server 2003 and Windows XP operating systems uses the weak host model. The TCP/IP stack on Windows Vista and later versions of the Windows operating systems supports the strong host model for both IPv4 and IPv6 and is configured to use the strong host mode by default (the **WeakHostReceive** and **WeakHostSend** members are set to **FALSE**). You can configure the TCP/IP stack on Windows Vista and later to use a weak host model.

A metric is a value that is assigned to an IP route for a particular network interface that identifies the cost that is associated with using that route. For example, the metric can be valued in terms of link speed, hop count, or time delay. Automatic metric is a feature on Windows XP and later that automatically configures the metric for the local routes that are based on link speed. By default, the automatic metric feature is enabled (the **UseAutomaticMetric** is set to **TRUE**) on Windows XP and later. You can also manually configure this feature to assign a specific metric to an IP route.

The automatic metric feature can be useful when the routing table contains multiple routes for the same destination. For example, a computer that has a 10 megabit network interface and a 100 megabit network interface has a default gateway that is configured on both network interfaces. When **UseAutomaticMetric** is **TRUE**, this feature can force all traffic that is destined for the Internet, for example, to use the fastest network interface that is available.

The interface metric that is specified in the **Metric** member represents only the metric for the interface. The complete routing metric is a combination of this interface metric added to the route metric offset that is specified in the **Metric** member of the MIB_IPFORWARD_ROW2 structure of a route entry that is specified on this interface.

Unprivileged simultaneous access to multiple networks of different security requirements creates a security hole and enables an unprivileged driver to accidentally relay data between the two networks. A typical example is simultaneous access to a virtual private network (VPN) and the Internet. Windows Server 2003 and Windows XP use a weak host model, where Remote Access Service (RAS) prevents such simultaneous access by increasing the route metric of all default routes over other interfaces. Therefore, all traffic is routed through the VPN interface, disrupting other network connectivity.

On Windows Vista and later, by default, a strong host model is used. If a source IP address is specified in the route lookup by using the GetBestRoute2 function, the route lookup is restricted to the interface of the source IP address. The route metric modification by RAS has no effect because the list of potential routes does not even have the route for the VPN interface, which enables traffic to the Internet. Your driver can use the **DisableDefaultRoutes** member of the MIB_IPINTERFACE_ROW structure to disable using the default route on an interface. VPN clients can use this member as a security measure to restrict split tunneling when split tunneling is not required by the VPN client. A VPN client can call the SetIpInterfaceEntry function to set the **DisableDefaultRoutes** member to **TRUE** when it is required. A VPN client can query the current state of the **DisableDefaultRoutes** member by calling the GetIpInterfaceEntry function.

MIB_IPINTERFACE_TABLE structure

Article • 03/03/2023

The MIB_IPINTERFACE_TABLE structure contains a table of IP interface entries.

Syntax

C++

```
typedef struct _MIB_IPINTERFACE_TABLE {
  ULONG               NumEntries;
  MIB_IPINTERFACE_ROW Table[ANY_SIZE];
} MIB_IPINTERFACE_TABLE, *PMIB_IPINTERFACE_TABLE;
```

Members

- **NumEntries**

  The number of IP interface entries in the array.

- **Table**

  An array of MIB_IPINTERFACE_ROW structures that contain IP interface entries.

Remarks

The GetIpInterfaceTable function enumerates the IP interface entries on a local computer and returns this information in a MIB_IPINTERFACE_TABLE structure.

The MIB_IPINTERFACE_TABLE structure might contain padding for alignment between the **NumEntries** member and the first MIB_IPINTERFACE_ROW array entry in the **Table** member. Padding for alignment might also be present between the MIB_IPINTERFACE_ROW array entries in the **Table** member. Any access to a MIB_IPINTERFACE_ROW array entry should assume padding might exist.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IPINTERFACE_ROW

MIB_IPNET_ROW2 structure

Article • 03/03/2023

The MIB_IPNET_ROW2 structure stores information about a neighbor IP address.

Syntax

C++

```
typedef struct _MIB_IPNET_ROW2 {
  SOCKADDR_INET     Address;
  NET_IFINDEX       InterfaceIndex;
  NET_LUID          InterfaceLuid;
  UCHAR             PhysicalAddress[IF_MAX_PHYS_ADDRESS_LENGTH];
  ULONG             PhysicalAddressLength;
  NL_NEIGHBOR_STATE State;
  union {
    struct {
      BOOLEAN IsRouter   :1;
      BOOLEAN IsUnreachable  :1;
    };
    UCHAR  Flags;
  };
  union {
    ULONG LastReachable;
    ULONG LastUnreachable;
  } ReachabilityTime;
} MIB_IPNET_ROW2, *PMIB_IPNET_ROW2;
```

Members

- **Address**

  The neighbor IP address. This member can be an IPv6 address or an IPv4 address.

- **InterfaceIndex**

  The local index value for the network interface that is associated with this IP address. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **InterfaceLuid**

  The locally unique identifier (LUID) for the network interface that is associated with this IP address.

- **PhysicalAddress**
  The physical hardware address of the adapter for the network interface that is associated with this IP address.

- **PhysicalAddressLength**
  The length, in bytes, of the physical hardware address that the **PhysicalAddress** member specifies. The maximum value that is supported is 32 bytes.

- **State**
  An NL_NEIGHBOR_STATE network layer neighbor state type.

- **IsRouter**
  A value that indicates if this IP address is a router.

- **IsUnreachable**
  A value that indicates if this IP address is unreachable.

- **Flags**
  A set of flags that indicate whether the IP address is a router and whether the IP address is unreachable.

- **ReachabilityTime**
  The time that the node assumes that the neighbor is reachable or unreachable after the node receives information about the reachability of the neighbor.

  This union contains the following members:

  - **LastReachable**
    The time, in milliseconds, that a node assumes that the neighbor will remain reachable after the node receives a reachability confirmation from the neighbor.

  - **LastUnreachable**
    The time, in milliseconds, that a node assumes that the neighbor will remain unreachable after the node fails to receive a reachability confirmation from the neighbor.

Remarks

The GetIpNetTable2 function enumerates the neighbor IP addresses on a local computer and returns this information in an MIB_IPNET_TABLE2 structure. For IPv4, this information includes addresses determined by using the Address Resolution Protocol (ARP). For IPv6, this information includes addresses determined by using the Neighbor Discovery (ND) protocol for IPv6 as specified in RFC 2461. For more information, see Neighbor Discovery for IP Version 6 (IPv6).

The GetIpNetEntry2 function retrieves a single neighbor IP address and returns this information in a MIB_IPNET_ROW2 structure.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

  ULONG64       LinkTransmitSpeed;
  ULONG64       LinkReceiveSpeed;
} MIB_IPPATH_ROW, *PMIB_IPPATH_ROW;
```

Members

- **Source**

  The source IP address for this IP path entry.

- **Destination**

  The destination IP address for this IP path entry.

- **InterfaceLuid**

  The locally unique identifier (LUID) for the network interface that is associated with this IP path entry.

- **InterfaceIndex**

  The local index value for the network interface that is associated with this IP path entry. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **CurrentNextHop**
  The current IP address of the next system or gateway that is along the route. This member can change over the lifetime of a path.

- **PathMtu**
  The maximum transmission unit (MTU) size, in bytes, to the destination IP address for this IP path entry.

- **RttMean**
  The estimated mean round-trip time (RTT), in milliseconds, to the destination IP address for this IP path entry.

- **RttDeviation**
  The estimated mean deviation for the round-trip time (RTT), in milliseconds, to the destination IP address for this IP path entry.

- **LastReachable**
  The time, in milliseconds, that a node assumes that the destination IP address is reachable after having received a reachability confirmation.

- **LastUnreachable**
  The time, in milliseconds, that a node assumes that the destination IP address is unreachable after not having received a reachability confirmation.

- **IsReachable**
  A value that indicates if the destination IP address is reachable for this IP path entry.

- **LinkTransmitSpeed**
  The estimated speed, in bits per second, of the transmit link to the destination IP address for this IP path entry.

- **LinkReceiveSpeed**
  The estimated speed, in bits per second, of the receive link from the destination IP address for this IP path entry.

Remarks

The **GetIpPathTable** function enumerates the IP path entries on a local computer and returns this information in a **MIB_IPPATH_TABLE** structure as an array of MIB_IPPATH_ROW entries.

The **GetIpPathTable** function retrieves a single IP path entry and returns this information in a **MIB_IPPATH_TABLE** structure.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_IPPATH_TABLE

MIB_IPPATH_TABLE structure

Article • 03/03/2023

The MIB_IPPATH_TABLE structure contains a table of IP path entries.

Syntax

```
C++

typedef struct _MIB_IPPATH_TABLE {
  ULONG          NumEntries;
  MIB_IPPATH_ROW Table[ANY_SIZE];
} MIB_IPPATH_TABLE, *PMIB_IPPATH_TABLE;
```

Members

- **NumEntries**

  A value that specifies the number of IP path entries in the array.

- **Table**

  An array of MIB_IPPATH_ROW structures that contain IP path entries.

Remarks

The GetIpPathTable function enumerates the IP path entries on a local computer and returns this information in a MIB_IPPATH_TABLE structure. The FlushIpPathTable function flushes the IP path table entries on a local computer.

The GetIpPathEntry function retrieves a single IP path entry and returns this information in a MIB_IPPATH_ROW structure.

The MIB_IPPATH_TABLE structure might contain padding for alignment between the **NumEntries** member and the first MIB_IPPATH_ROW array entry in the **Table** member. Padding for alignment might also be present between the MIB_IPPATH_ROW array entries in the **Table** member. Any access to a MIB_IPPATH_ROW array entry should assume padding might exist.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

Header	Netioapi.h (include Netioapi.h)

MIB_IPPATH_ROW

MIB_MULTICASTIPADDRESS_ROW structure

Article • 03/03/2023

The MIB_MULTICASTIPADDRESS_ROW structure stores information about a multicast IP address.

Syntax

```c++
typedef struct _MIB_MULTICASTIPADDRESS_ROW {
  SOCKADDR_INET Address;
  NET_IFINDEX   InterfaceIndex;
  NET_LUID      InterfaceLuid;
  SCOPE_ID      ScopeId;
} MIB_MULTICASTIPADDRESS_ROW, *PMIB_MULTICASTIPADDRESS_ROW;
```

Members

- **Address**
  The multicast IP address. This member can be an IPv6 address or an IPv4 address.

- **InterfaceIndex**
  The local index value for the network interface that is associated with this IP address. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **InterfaceLuid**
  The locally unique identifier (LUID) for the network interface that is associated with this IP address.

- **ScopeId**
  The scope ID of the multicast IP address. This member is applicable only to an IPv6 address. Your driver cannot set this member. This member is automatically determined by the interface that the address was added on.

Remarks

The GetMulticastIpAddressTable function enumerates the multicast IP addresses on a local computer and returns this information in a MIB_MULTICASTIPADDRESS_TABLE structure. The **GetMulticastIpAddressEntry** function retrieves a single multicast IP address and returns this information in a MIB_MULTICASTIPADDRESS_ROW structure.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_MULTICASTIPADDRESS_ROW

MIB_UNICASTIPADDRESS_ROW structure

Article • 03/03/2023

The MIB_UNICASTIPADDRESS_ROW structure stores information about a unicast IP address.

Syntax

C++

```
typedef struct _MIB_UNICASTIPADDRESS_ROW {
  SOCKADDR_INET    Address;
  NET_LUID         InterfaceLuid;
  NET_IFINDEX      InterfaceIndex;
  NL_PREFIX_ORIGIN PrefixOrigin;
  NL_SUFFIX_ORIGIN SuffixOrigin;
  ULONG            ValidLifetime;
  ULONG            PreferredLifetime;
  UINT8            OnLinkPrefixLength;
  BOOLEAN          SkipAsSource;
  NL_DAD_STATE     DadState;
  SCOPE_ID         ScopeId;
  LARGE_INTEGER    CreationTimeStamp;
} MIB_UNICASTIPADDRESS_ROW, *PMIB_UNICASTIPADDRESS_ROW;
```

Members

- **Address**
  The unicast IP address. This member can be an IPv6 address or an IPv4 address.

- **InterfaceLuid**
  The locally unique identifier (LUID) for the network interface that is associated with this IP address.

- **InterfaceIndex**
  The local index value for the network interface that is associated with this IP address. This index value might change when a network adapter is disabled and then enabled, or under other circumstances, and should not be considered persistent.

- **PrefixOrigin**
  An NL_PREFIX_ORIGIN type that specifies the origin of the prefix or network part of the IP address.

- **SuffixOrigin**
  An NL_SUFFIX_ORIGIN type that specifies the origin of the suffix or host part of the IP address.

- **ValidLifetime**
  The maximum time, in seconds, that the IP address is valid. A value of 0xffffffff is considered to be infinite.

- **PreferredLifetime**
  The preferred time, in seconds, that the IP address is valid. A value of 0xffffffff is considered to be infinite.

- **OnLinkPrefixLength**
  The length, in bits, of the prefix or network part of the IP address. For a unicast IPv4 address, any value that is greater than 32 is an illegal value. For a unicast IPv6 address, any value that is greater than 128 is an illegal value. A value of 255 is typically used to represent an illegal value.

- **SkipAsSource**
  A value that specifies if the address can be used as an IP source address.

- **DadState**
  A NL_DAD_STATE duplicate address detection (DAD) type.

- **ScopeId**
  The scope ID of the IP address. This member is applicable only to an IPv6 address. Your driver cannot set this member. This member is automatically determined by the interface that the address was added on.

- **CreationTimeStamp**
  The time stamp when the IP address was created.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.

MIB_UNICASTIPADDRESS_TABLE structure

Article • 03/03/2023

The MIB_UNICASTIPADDRESS_TABLE structure contains a table of unicast IP address entries.

Syntax

```C++
typedef struct _MIB_UNICASTIPADDRESS_TABLE {
  ULONG                    NumEntries;
  MIB_UNICASTIPADDRESS_ROW Table[ANY_SIZE];
} MIB_UNICASTIPADDRESS_TABLE, *PMIB_UNICASTIPADDRESS_TABLE;
```

Members

- **NumEntries**
  A value that specifies the number of unicast IP address entries in the array.

- **Table**
  An array of MIB_UNICASTIPADDRESS_ROW structures that contains unicast IP address entries.

Remarks

The GetUnicastIpAddressTable function enumerates the unicast IP addresses on a local computer and returns this information in an MIB_UNICASTIPADDRESS_TABLE structure.

The MIB_UNICASTIPADDRESS_TABLE structure might contain padding for alignment between the **NumEntries** member and the first MIB_UNICASTIPADDRESS_ROW array entry in the **Table** member. Padding for alignment might also be present between the MIB_UNICASTIPADDRESS_ROW array entries in the **Table** member. Any access to a MIB_UNICASTIPADDRESS_ROW array entry should assume padding might exist.

NL_DAD_STATE enumeration

Article • 03/03/2023

The NL_DAD_STATE enumeration type defines the duplicate address detection (DAD) state.

Syntax

C++

```
typedef enum  {
  NldsInvalid,
  NldsTentative,
  NldsDuplicate,
  NldsDeprecated,
  NldsPreferred,
  IpDadStateInvalid     = 0,
  IpDadStateTentative,
  IpDadStateDuplicate,
  IpDadStateDeprecated,
  IpDadStatePreferred
} NL_DAD_STATE;
```

Constants

- **NldsInvalid**
  Reserved for system use. Do not use this value in your driver.

- **NldsTentative**
  Reserved for system use. Do not use this value in your driver.

- **NldsDuplicate**
  Reserved for system use. Do not use this value in your driver.

- **NldsDeprecated**
  Reserved for system use. Do not use this value in your driver.

- **NldsPreferred**
  Reserved for system use. Do not use this value in your driver.

- **IpDadStateInvalid**
  The DAD state is invalid.

- **IpDadStateTentative**
  The DAD state is tentative.

- **IpDadStateDuplicate**
  A duplicate IP address has been detected.

- **IpDadStateDeprecated**
  The IP address has been deprecated.

- **IpDadStatePreferred**
  The IP address is the preferred address.

Remarks

The DAD state applies to both IPv4 and IPv6 addresses.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Nldef.h (include Netioapi.h)

NL_PREFIX_ORIGIN enumeration

Article • 03/03/2023

The NL_PREFIX_ORIGIN enumeration type defines the origin of the prefix or network part of the IP address.

Syntax

C++

```
typedef enum  {
  IpPrefixOriginOther                 = 0,
  IpPrefixOriginManual,
  IpPrefixOriginWellKnown,
  IpPrefixOriginDhcp,
  IpPrefixOriginRouterAdvertisement,
  IpPrefixOriginUnchanged             = 1 << 4
} NL_PREFIX_ORIGIN;
```

Constants

- **IpPrefixOriginOther**
  The IP address prefix was configured by using a source other than those that are defined in this enumeration. This value applies to an IPv6 or IPv4 address.

- **IpPrefixOriginManual**
  The IP address prefix was configured manually. This value applies to an IPv6 or IPv4 address.

- **IpPrefixOriginWellKnown**
  The IP address prefix was configured by using a well-known address. This value applies to an IPv6 link-local address or an IPv6 loopback address.

- **IpPrefixOriginDhcp**
  The IP address prefix was configured by using DHCP. This value applies to an IPv4 address configured by using DHCP or an IPv6 address configured by using DHCPv6.

- **IpPrefixOriginRouterAdvertisement**
  The IP address prefix was configured by using router advertisement. This value applies to an anonymous IPv6 address that was generated after receiving a router advertisement.

- **IpPrefixOriginUnchanged**
  The IP address prefix should be unchanged. This value is used when setting the properties for a unicast IP interface when the value for the IP prefix origin should be unchanged.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Nldef.h (include Netioapi.h)

NL_SUFFIX_ORIGIN enumeration

Article • 03/03/2023

The NL_SUFFIX_ORIGIN enumeration type defines the origin of the suffix or host part of the IP address.

Syntax

C++

```
typedef enum  {
  NlsoOther,
  NlsoManual,
  NlsoWellKnown,
  NlsoDhcp,
  NlsoLinkLayerAddress,
  NlsoRandom,
  IpSuffixOriginOther             = 0,
  IpSuffixOriginManual,
  IpSuffixOriginWellKnown,
  IpSuffixOriginDhcp,
  IpSuffixOriginLinkLayerAddress,
  IpSuffixOriginRandom,
  IpSuffixOriginUnchanged         = 1 << 4
} NL_SUFFIX_ORIGIN;
```

Constants

- **NlsoOther**
  Reserved for system use. Do not use this value in your driver.

- **NlsoManual**
  Reserved for system use. Do not use this value in your driver.

- **NlsoWellKnown**
  Reserved for system use. Do not use this value in your driver.

- **NlsoDhcp**
  Reserved for system use. Do not use this value in your driver.

- **NlsoLinkLayerAddress**
  Reserved for system use. Do not use this value in your driver.

- **NlsoRandom**
  Reserved for system use. Do not use this value in your driver.

- **IpSuffixOriginOther**
  The IP address suffix was configured by using a source other than those that are defined in this enumeration. This value applies to an IPv6 or IPv4 address.

- **IpSuffixOriginManual**
  The IP address suffix was configured manually. This value applies to an IPv6 or IPv4 address.

- **IpSuffixOriginWellKnown**
  The IP address suffix was configured by using a well-known address. This value applies to an IPv6 link-local address or an IPv6 loopback address.

- **IpSuffixOriginDhcp**
  The IP address suffix was configured by using DHCP. This value applies to an IPv4 address configured by using DHCP or an IPv6 address configured by using DHCPv6.

- **IpSuffixOriginLinkLayerAddress**
  The IP address suffix was the link-local address. This value applies to an IPv6 link-local address or an IPv6 address where the network part was generated based on a router advertisement and the host part was based on the MAC hardware address.

- **IpSuffixOriginRandom**
  The IP address suffix was generated randomly. This value applies to an anonymous IPv6 address where the host part of the address was generated randomly from the MAC hardware address after the host received a router advertisement.

- **IpSuffixOriginUnchanged**
  The IP address suffix should be unchanged. This value is used when setting the properties for a unicast IP interface when the value for the IP suffix origin should be unchanged.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Nldef.h (include Netioapi.h)

CancelMibChangeNotify2 function

Article • 03/03/2023

The **CancelMibChangeNotify2** function deregisters a driver change notification for IP interface changes, IP address changes, IP route changes, and requests to retrieve the stable Unicast IP address table.

Syntax

```c++
NETIOAPI_API CancelMibChangeNotify2(
  _In_ HANDLE NotificationHandle
);
```

Parameters

- *NotificationHandle* [in]
  The handle that is returned from a notification registration or retrieval function to indicate which notification to cancel.

Return value

CancelMibChangeNotify2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **CancelMibChangeNotify2** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. **CancelMibChangeNotify2** returns this error if the *NotificationHandle* parameter was a **NULL** pointer.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **CancelMibChangeNotify2** function deregisters a driver change notification previously requested for IP interface changes, IP address changes, or IP route changes on a local computer. These requests are made by calling NotifyIpInterfaceChange, NotifyRouteChange2, or NotifyUnicastIpAddressChange. The **CancelMibChangeNotify2** function also cancels a previous request to retrieve the stable unicast IP address table on a local computer. This request is made by calling the NotifyStableUnicastIpAddressTable function.

The *NotificationHandle* parameter that is returned to these notification functions is passed to **CancelMibChangeNotify2** to deregister driver change notifications or to cancel a pending request to retrieve the stable unicast IP address table.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	PASSIVE_LEVEL

See also

NotifyIpInterfaceChange

NotifyRouteChange2

NotifyStableUnicastIpAddressTable

NotifyUnicastIpAddressChange

NotifyIpInterfaceChange function

Article • 03/03/2023

The **NotifyIpInterfaceChange** function registers the driver to be notified for changes to all IP interfaces, IPv4 interfaces, or IPv6 interfaces on a local computer.

Syntax

C++

```
NETIOAPI_API NotifyIpInterfaceChange(
  _In_    ADDRESS_FAMILY               Family,
  _In_    PIPINTERFACE_CHANGE_CALLBACK Callback,
  _In_    PVOID                        CallerContext,
  _In_    BOOLEAN                      InitialNotification,
  _Inout_ HANDLE                       *NotificationHandle
);
```

Parameters

- *Family* [in]
  The address family to register the driver for change notifications on.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function registers the driver to be notified only for IPv4 change notifications.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function registers the driver for only IPv6 change notifications.

    - AF_UNSPEC
      The address family is unspecified. When this value is specified, this function registers the driver to be notified for both IPv4 and IPv6 changes.

- *Callback* [in]
  A pointer to the function to call when a change occurs. This function is called when an interface notification is received.

- *CallerContext* [in]
  A user context that is passed to the callback function that is specified in the *Callback* parameter when an interface notification is received.

- *InitialNotification* [in]
  A value that indicates whether the callback should be invoked immediately after registration for change notification completes. This initial notification does not indicate a change occurred to an IP interface. The purpose of this parameter to provide confirmation that the callback is registered.

- *NotificationHandle* [in, out]
  A pointer used to return a handle that can be later used to deregister the change notification. On success, a notification handle is returned in this parameter. If an error occurs, **NULL** is returned.

Return value

NotifyIpInterfaceChange returns STATUS_SUCCESS if the function succeeds.

If the function fails, **NotifyIpInterfaceChange** returns one of the following error codes:

Return code	Description
ERROR_INVALID_HANDLE	An internal error occurred where an invalid handle was encountered.
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Family* parameter was not either AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	There was insufficient memory.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must set the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

The invocation of the callback function that is specified in the *Callback* parameter is serialized. The callback function should be defined as a function of type **VOID**. The parameters that are passed to the callback function include the following.

Parameter	Description
IN PVOID *CallerContext*	The *CallerContext* parameter that is passed to the **NotifyIpInterfaceChange** function when it is registering the driver for change notifications.
IN PMIB_IPINTERFACE_ROW *Row* OPTIONAL	A pointer to the MIB_IPINTERFACE_ROW entry for the interface that was changed. This parameter is a **NULL** pointer when the MIB_NOTIFICATION_TYPE value that is passed in the *NotificationType* parameter to the callback function is set to **MibInitialNotification**. This situation can occur only if the *InitialNotification* parameter that is passed to **NotifyIpInterfaceChange** was set to **TRUE** when registering the driver for change notifications.
IN MIB_NOTIFICATION_TYPE *NotificationType*	The notification type. This member can be one of the values from the MIB_NOTIFICATION_TYPE enumeration type.

To deregister the driver for change notifications, call the CancelMibChangeNotify2 function, passing the *NotificationHandle* parameter that **NotifyIpInterfaceChange** returns.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

NotifyRouteChange2 function

Article • 03/03/2023

The **NotifyRouteChange2** function registers the driver to be notified for changes to IP route entries on a local computer.

Syntax

C++

```
NETIOAPI_API NotifyRouteChange2(
  _In_    ADDRESS_FAMILY            Family,
  _In_    PIPFORWARD_CHANGE_CALLBACK Callback,
  _In_    PVOID                     CallerContext,
  _In_    BOOLEAN                   InitialNotification,
  _Inout_ HANDLE                    *NotificationHandle
);
```

Parameters

- *Family* [in]
  The address family to register the driver for change notifications on.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, this function registers the driver only for IPv4 route change notifications.

  - AF_INET6
    The IPv6 address family. When this value is specified, this function registers the driver only for IPv6 route change notifications.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, this function registers the driver for both IPv4 and IPv6 route change notifications.

- *Callback* [in]
  A pointer to the function to call when a change occurs. This function is called when an interface notification is received.

- *CallerContext* [in]
  A user context that is passed to the callback function that is specified in the *Callback* parameter when an interface notification is received.

- *InitialNotification* [in]
  A value that indicates whether the callback should be invoked immediately after registration for change notification completes. This initial notification does not indicate a change occurred to the IP route. The purpose of this parameter to provide confirmation that the callback is registered.

- *NotificationHandle* [in, out]
  A pointer to a MIB_IPINTERFACE_ROW structure to initialize. On successful return, the members in this structure are initialized with default information for an interface on the local computer.

Return value

NotifyRouteChange2 returns STATUS_SUCCESS if the function succeeds.

If the function fails, **NotifyRouteChange2** returns one of the following error codes.

Return code	Description
ERROR_INVALID_HANDLE	An internal error occurred where an invalid handle was encountered.
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Family* parameter was not either AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	There was insufficient memory.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must set the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

The invocation of the callback function that is specified in the *Callback* parameter is serialized. The callback function should be defined as a function of type **VOID**. The parameters that are passed to the callback function include the following.

Parameter	Description
IN PVOID *CallerContext*	The *CallerContext* parameter that is passed to the **NotifyRouteChange2** function when it is registering the driver for change notifications.
IN PMIB_IPFORWARD_ROW2 *Row* OPTIONAL	A pointer to the MIB_IPFORWARD_ROW2 entry for the IP route entry that was changed. This parameter is a **NULL** pointer when the MIB_NOTIFICATION_TYPE value that is passed in the *NotificationType* parameter to the callback function is set to MibInitialNotification. This situation can occur only if the *InitialNotification* parameter that is passed to **NotifyRouteChange2** was set to **TRUE** when registering the driver for change notifications.
IN MIB_NOTIFICATION_TYPE *NotificationType*	The notification type. This member can be one of the values from the MIB_NOTIFICATION_TYPE enumeration type.

To deregister the driver for change notifications, call the CancelMibChangeNotify2 function, passing the *NotificationHandle* parameter that **NotifyRouteChange2** returns.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

NotifyUnicastIpAddressChange function

Article • 03/03/2023

The **NotifyUnicastIpAddressChange** function registers the driver to be notified for changes to all unicast IP interfaces, unicast IPv4 addresses, or unicast IPv6 addresses on a local computer.

Syntax

C++

```
NETIOAPI_API NotifyUnicastIpAddressChange(
  _In_    ADDRESS_FAMILY                    Family,
  _In_    PUNICAST_IPADDRESS_CHANGE_CALLBACK Callback,
  _In_    PVOID                             CallerContext,
  _In_    BOOLEAN                           InitialNotification,
  _Inout_ HANDLE                            *NotificationHandle
);
```

Parameters

- *Family* [in]
  The address family to register the driver for change notifications on.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, the function registers the driver only for unicast IPv4 address change notifications.

  - AF_INET6
    The IPv6 address family. When this value is specified, the function registers the driver only for unicast IPv6 address change notifications.

- AF_UNSPEC
  The address family is unspecified. When this value is specified, the function registers the driver for both unicast IPv4 and IPv6 address change notifications.

- *Callback* [in]
  A pointer to the function to call when a change occurs. This function is called when a unicast IP address notification is received.

- *CallerContext* [in]
  A user context that is passed to the callback function that is specified in the *Callback* parameter when an interface notification is received.

- *InitialNotification* [in]
  A value that indicates whether the callback should be called immediately after registration for change notification completes. This initial notification does not indicate that a change occurred to a unicast IP address. This parameter provides confirmation that the callback is registered.

- *NotificationHandle* [in, out]
  A pointer that is used to return a handle that your driver can later use to deregister the driver change notification. On success, a notification handle is returned in this parameter. If an error occurs, **NULL** is returned.

Return value

NotifyUnicastIpAddressChange returns STATUS_SUCCESS if the function succeeds.

If the function fails, **NotifyUnicastIpAddressChange** returns one of the following error codes:

Return code	Description
ERROR_INVALID_HANDLE	An internal error occurred where an invalid handle was encountered.
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Family* parameter was not either AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	There was insufficient memory.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

Your driver must set the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

The invocation of the callback function that is specified in the *Callback* parameter is serialized. The callback function should be defined as a function of type **VOID**. The parameters that are passed to the callback function include the following.

Parameter	Description
IN PVOID *CallerContext*	The *CallerContext* parameter that is passed to the **NotifyUnicastIpAddressChange** function when it is registering the driver for change notifications.
IN PMIB_UNICASTIPADDRESS_ROW *Row* OPTIONAL	A pointer to the MIB_UNICASTIPADDRESS_ROW entry for the unicast IP address that was changed. This parameter is a **NULL** pointer when the MIB_NOTIFICATION_TYPE value that is passed in the *NotificationType* parameter to the callback function is set to **MibInitialNotification**. This situation can occur only if the *InitialNotification* parameter that is passed to **NotifyUnicastIpAddressChange** was set to **TRUE** when registering the driver for change notifications.
IN MIB_NOTIFICATION_TYPE *NotificationType*	The notification type. This member can be one of the values from the MIB_NOTIFICATION_TYPE enumeration type.

To deregister the driver for change notifications, call the CancelMibChangeNotify2 function, passing the *NotificationHandle* parameter that **NotifyUnicastIpAddressChange** returns.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

GetTeredoPort function

Article • 03/03/2023

The **GetTeredoPort** function retrieves the dynamic UDP port number that the Teredo client uses on a local computer.

Syntax

```
C++

NETIOAPI_API GetTeredoPort(
  _Out_ USHORT *Port
);
```

Parameters

- *Port* [out]
  A pointer to the UDP port number. On successful return, this parameter is filled with the port number that the Teredo client uses.

Return value

GetTeredoPort returns STATUS_SUCCESS if the function succeeds.

If the function fails, **GetTeredoPort** returns one of the following error codes:

Return code	Description
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if a **NULL** pointer is passed in the *Port* parameter.
ERROR_NOT_READY	The device is not ready. This error is returned if the Teredo client is not started on the local computer.
STATUS_NOT_SUPPORTED	The request is not supported. This error is returned if no IPv6 stack is located on the local computer.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The **GetTeredoPort** function retrieves the current UDP port number that the Teredo client usesfor the Teredo service port. The Teredo port is dynamic and can change any time that the Teredo client is restarted on the local computer. A driver can register to be notified when the Teredo service port changes by calling the **NotifyTeredoPortChange** function.

The Teredo client also uses static UDP port 3544 for listening to multicast traffic that is sent on multicast IPv4 address 224.0.0.253 as defined in RFC 4380. For more information, see Teredo: Tunneling IPv6 over UDPthrough Network Address Translations (NATs) .

The **GetTeredoPort** function is used primarily by firewall drivers in order to configure the appropriate exceptions to enable incoming and outgoing Teredo traffic.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

NotifyStableUnicastIpAddressTable

NotifyStableUnicastIpAddressTable function

Article • 03/03/2023

The **NotifyStableUnicastIpAddressTable** function retrieves the stable unicast IP address table on a local computer.

Syntax

```
C++

NETIOAPI_API NotifyStableUnicastIpAddressTable(
  _In_    ADDRESS_FAMILY                          Family,
  _Out_   PMIB_UNICASTIPADDRESS_TABLE             *Table,
  _In_    PSTABLE_UNICAST_IPADDRESS_TABLE_CALLBACK CallerCallback,
  _In_    PVOID                                   CallerContext,
  _Inout_ HANDLE                                  *NotificationHandle
);
```

Parameters

- *Family* [in]
  The address family to retrieve.

  Possible values for the address family are listed in the Winsock2.h header file. Note that the values for the AF_ address family and PF_ protocol family constants are identical (for example, AF_INET and PF_INET), so you can use either constant.

  On Windows Vista and later versions of the Windows operating systems, possible values for the *Family* parameter are defined in the Ws2def.h header file. Note that the Ws2def.h header file is automatically included in Netioapi.h and you should never use Ws2def.h directly.

  The following values are currently supported for the address family:

  - AF_INET
    The IPv4 address family. When this value is specified, the function retrieves the stable unicast IP address table that contains only IPv4 entries.

  - AF_INET6
    The IPv6 address family. When this value is specified, the function retrieves the

stable unicast IP address table that contains only IPv6 entries.

  - AF_UNSPEC
    The address family is unspecified. When this value is specified, the function retrieves the stable unicast IP address table that contains both IPv4 and IPv6 entries.

- *Table* [out]
  A pointer to a MIB_UNICASTIPADDRESS_TABLE structure. When **NotifyStableUnicastIpAddressTable** is successful, this parameter returns the stable unicast IP address table on the local computer.

  When **NotifyStableUnicastIpAddressTable** returns ERROR_IO_PENDING, which indicates that the I/O request is pending, the stable unicast IP address table is returned to the function in the *CallerCallback* parameter.

- *CallerCallback* [in]
  A pointer to the function to call with the stable unicast IP address table. This function is called if **NotifyStableUnicastIpAddressTable** returns ERROR_IO_PENDING, which indicates that the I/O request is pending.

- *CallerContext* [in]
  A user context that is passed to the callback function that is specified in the *CallerCallback* parameter when the stable unicast IP address table is available.

- *NotificationHandle* [in, out]
  A pointer that is used to return a handle that your driver can use to cancel the request to retrieve the stable unicast IP address table. This parameter is returned if the return value from **NotifyStableUnicastIpAddressTable** is ERROR_IO_PENDING, which indicates that the I/O request is pending.

Return value

NotifyStableUnicastIpAddressTable returns STATUS_SUCCESS and the stable unicast IP table is returned in the *Table* parameter if the function succeeds immediately.

If the I/O request is pending, the function returns ERROR_IO_PENDING and the function that the *CallerCallback* parameter points to is called when the I/O request has completed with the stable unicast IP address table.

If the function fails, **NotifyStableUnicastIpAddressTable** returns one of the following error codes:

Return code	Description
ERROR_INVALID_HANDLE	An internal error occurred where an invalid handle was encountered.
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Table* parameter was a **NULL** pointer, the *NotificationHandle* parameter was a **NULL** pointer, or the *Family* parameter was not either AF_INET, AF_INET6, or AF_UNSPEC.
STATUS_NOT_ENOUGH_MEMORY	There was insufficient memory.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

All unicast IP addresses, except dial-on-demand addresses, are considered stable only if they are in the preferred state. For a normal unicast IP address entry, this state would correspond to a **DadState** member of the **MIB_UNICASTIPADDRESS_ROW** for the IP address that is set to **IpDadStatePreferred**. Every dial-on-demand address defines its own stability metric. Currently the only dial-on-demand address that the **NotifyStableUnicastIpAddressTable** function considers is the unicast IP address that the Teredo client uses on the local computer.

Your driver must set the *Family* parameter to either AF_INET, AF_INET6, or AF_UNSPEC.

When **NotifyStableUnicastIpAddressTable** is successful and returns STATUS_SUCCESS, the *Table* parameter returns the stable unicast IP address table on the local computer.

When **NotifyStableUnicastIpAddressTable** returns ERROR_IO_PENDING, which indicates that the I/O request is pending, the stable unicast IP address table is returned to the function in the *CallerCallback* parameter.

If the unicast IP address that Teredo uses is available on the local computer but not in the stable (qualified) state, **NotifyStableUnicastIpAddressTable** returns ERROR_IO_PENDING and the stable unicast IP address table is eventually returned by calling the function in the *CallerCallback* parameter. If the Teredo address is not available or is in the stable state and the other unicast IP addresses are in a stable state, the function in the *CallerCallback* parameter is never called.

The callback function that is specified in the *CallerCallback* parameter should be defined as a function of type **VOID**. The parameters that are passed to the callback function include the following.

Parameter	Description
IN PVOID *CallerContext*	The *CallerContext* parameter that is passed to the **NotifyStableUnicastIpAddressTable** function when it is registering the driver for notifications.
IN PMIB_UNICASTIPADDRESS_TABLE *AddressTable*	A pointer to a MIB_UNICASTIPADDRESS_TABLE structure that contains the stable unicast IP address table on the local computer.

The **NotifyStableUnicastIpAddressTable** function is used primarily by drivers that use the Teredo client.

To cancel the notification after the callback is complete, call the CancelMibChangeNotify2 function, passing the *NotificationHandle* parameter that **NotifyStableUnicastIpAddressTable** returns.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Netioapi.h (include Netioapi.h)
Library	Netio.lib
IRQL	< DISPATCH_LEVEL

NotifyTeredoPortChange function

Article • 03/03/2023

The **NotifyTeredoPortChange** function registers the driver to be notified for changes to the UDP port number that the Teredo client uses for the Teredo service port on a local computer.

Syntax

C++

```
NETIOAPI_API NotifyTeredoPortChange(
  _In_    PTEREDO_PORT_CHANGE_CALLBACK Callback,
  _In_    PVOID                        CallerContext,
  _In_    BOOLEAN                      InitialNotification,
  _Inout_ HANDLE *                     NotificationHandle
);
```

Parameters

- *Callback* [in]
  A pointer to the function to call when a Teredo client port change occurs. This function is called when a Teredo port change notification is received.

- *CallerContext* [in]
  A user context that is passed to the callback function that is specified in the Callback parameter when a Teredo port change notification is received.

- *InitialNotification* [in]
  A value that indicates whether the callback should be called immediately after registration for driver change notification completes. This initial notification does not indicate that a change occurred to the Teredo client port. This parameter provides confirmation that the callback is registered.

- *NotificationHandle* [in, out]
  A pointer that is used to return a handle that your driver can later use to deregister the driver change notification. On success, a notification handle is returned in this parameter. If an error occurs, **NULL** is returned.

Return value

NotifyTeredoPortChange returns STATUS_SUCCESS if the function succeeds.

If the function fails, **NotifyTeredoPortChange** returns one of the following error codes:

Return code	Description
ERROR_INVALID_HANDLE	An internal error occurred where an invalid handle was encountered.
STATUS_INVALID_PARAMETER	An invalid parameter was passed to the function. This error is returned if the *Callback* parameter is a **NULL** pointer.
STATUS_NOT_ENOUGH_MEMORY	There was insufficient memory.
Other	Use the FormatMessage function to obtain the message string for the returned error.

Remarks

The invocation of the callback function that is specified in the *Callback* parameter is serialized. The callback function should be defined as a function of type **VOID**. The parameters that are passed to the callback function include the following.

Parameter	Description
IN PVOID *CallerContext*	The *CallerContext* parameter that is passed to the **NotifyTeredoPortChange** function when it is registering the driver for change notifications.
IN USHORT *Port*	The UDP port number that the Teredo client currently uses. This parameter is zero when the **MIB_NOTIFICATION_TYPE** value that is passed in the *NotificationType* parameter to the callback function is set to **MibInitialNotification**. This situation can occur only if the *InitialNotification* parameter that is passed to **NotifyTeredoPortChange** was set to **TRUE** when registering the driver for change notifications.
IN MIB_NOTIFICATION_TYPE *NotificationType*	The notification type. This member can be one of the values from the **MIB_NOTIFICATION_TYPE** enumeration type.

Your driver can use the **GetTeredoPort** function to retrieve the initial UDP port number that the Teredo client used for the Teredo service port.

The Teredo port is dynamic and can change any time that the Teredo client is restarted on the local computer. A driver can register to be notified when the Teredo service port changes by calling the **NotifyTeredoPortChange** function.

The Teredo client also uses static UDP port 3544 for listening to multicast traffic that is sent on multicast IPv4 address 224.0.0.253 as defined in RFC 4380. For more information, see Teredo: Tunneling IPv6 over UDPthrough Network Address Translations (NATs) .

The **NotifyTeredoPortChange** function is used primarily by firewall drivers to configure the appropriate exceptions to enable incoming and outgoing Teredo traffic.

To deregister the driver for change notifications, call the **CancelMibChangeNotify2** function, passing the *NotificationHandle* parameter that the **NotifyTeredoPortChange** function returns.

Requirements

Target platform	Universal
Version	Available in Windows Vista and later versions of the Windows operating systems.

Roadmap for Developing WFP Callout Drivers

Article • 11/29/2022

To create a Windows Filtering Platform (WFP) callout driver, follow these steps:

- Step 1: Learn about WFP architecture.

  For information about WFP, see Windows Filtering Platform. You may find that you can develop a WFP user-mode application and avoid writing a WFP callout driver.

- Step 2: Learn about Windows architecture and drivers.

  You must understand the fundamentals of how drivers work in Windows operating systems. Knowing the fundamentals will help you make appropriate design decisions and let you streamline your development process. For more information about driver fundamentals, see Concepts for all driver developers.

- Step 3: Determine the Windows driver model for your WFP callout driver.

  WFP callout drivers can be written either by using the Windows Driver Model (WDM) or the Kernel Mode Driver Framework (KMDF). For more information about how to select a driver model, see Choosing a Driver Model. For more information about WDM, see Introduction to Windows Drivers and Writing WDM Drivers. For more information about KMDF, see WDF Driver Development Guide.

- Step 4: Determine additional Windows driver design decisions.

  For information about how to make additional Windows design decisions, see Creating Reliable Kernel-Mode Drivers, Programming Issues for 64-Bit Drivers, and Creating International INF Files.

- Step 5: Learn about the Windows driver build, test, and debug processes and tools.

  Building a driver differs from building a user-mode application. For information about Windows driver build, debug, and test processes, driver signing, and Windows Hardware Lab Kit (HLK) testing, see Building, Debugging, and Testing Drivers. For information about building, testing, verifying, and debugging tools, see Driver Development Tools.

- Step 6: Review the Windows Filtering Platform (WFP) driver samples in the Windows driver samples repository on GitHub.

- Step 7: Make design decisions about your WFP callout driver.

  For information about how to design WFP callout drivers, see Callout Driver Programming Considerations.

- Step 8: Develop, build, test, and debug your WFP callout driver.

  For information about WFP callout driver specifics, see Callout Driver Operations and Callout Driver Installation. For information about functions, structures, enumerations, or constants that are specific to WFP, see Windows Filtering Platform Callout Drivers Reference. For information about iterative building, testing, and debugging, see Overview of Build, Debug, and Test Process. This process will help ensure that you build a driver that works.

- Step 9: Create a driver package for your WFP callout driver.

  For more information, see Providing a Driver Package and Callout Driver Installation.

- Step 10: Sign and distribute your WFP callout driver.

  The final step is to sign (optional) and distribute the driver. If your driver meets the quality standards that are defined for the Windows Hardware Lab Kit (HLK), you can distribute it through the Microsoft Windows Update program. For more information about how to distribute a driver, see Get started with the hardware submission process.

These are the basic steps. Additional steps might be necessary based on the needs of your individual driver.

Introduction to Windows Filtering Platform (WFP) Callout Drivers

Article • 09/27/2024

This section introduces WFP callout drivers.

For more information about the WFP, see the Windows Filtering Platform documentation in the Microsoft Windows SDK.

For WFP reference information, see Windows Filtering Platform Callout Drivers.

Purpose of Callout Drivers

A callout driver implements one or more callouts. Callouts extend the capabilities of the Windows Filtering Platform by processing TCP/IP-based network data in ways that are beyond the scope of the simple filtering functionality. Callouts are typically used to do the following tasks:

Deep Inspection
Perform complex inspection of the network data to determine which data should be blocked, which data should be permitted, and which data should be passed to another filter. An antivirus product, for example, could look for virus signatures.

Packet Modification
Perform modification and reinjection of the network packet headers or data, or both. A network address translation (NAT) product, for example, could modify the headers on IPv4 packets.

Stream Modification
Perform modification and reinjection of the network data in a stream. A parental control product, for example, could remove or replace specific words or phrases in a data stream.

Data Logging
Log of network traffic data. A network monitoring product, for example, could count the number of data packets that are discarded for a specific reason.

In addition to processing network data, callout drivers can perform other Windows Filtering Platform management tasks, such as adding filters to the base filtering engine. For more information about other tasks that a callout driver can perform, see Calling Other Windows Filtering Platform Functions.

WFP Changes for Windows 8

Article • 12/15/2021

Several changes have been made in the available functions and behavior of the Windows Filtering Platform that begin with Windows 8. Frequently, to take advantage of the new features, you must compile or recompile a callout driver that has the NTDDI_VERSION macro set to NTDDI_WIN8.

- New features:
  - Using Layer 2 Filtering
  - Using Proxied Connections Tracking
  - Using Virtual Switch Filtering
- New functions:
  - **FwpsCalloutRegister2**
  - **FwpsFlowAbort0**
  - **FwpsInjectMacReceiveAsync0**
  - **FwpsInjectMacSendAsync0**
  - **FwpsNetBufferListAssociateContext1**
  - **FwpsQueryConnectionRedirectState0**
  - **FwpsRedirectHandleCreate0**
  - **FwpsRedirectHandleDestroy0**
  - **FwpsvSwitchEventsSubscribe0**
  - **FwpsvSwitchEventsUnsubscribe0**
  - **FwpsvSwitchNotifyComplete0**
- New callback functions:
  - *FWPS_CALLOUT_CLASSIFY_FN2*
  - *FWPS_CALLOUT_NOTIFY_FN2*
  - *FWPS_NET_BUFFER_LIST_NOTIFY_FN1*
  - *FWPS_VSWITCH_FILTER_ENGINE_REORDER_CALLBACK0*
  - *FWPS_VSWITCH_INTERFACE_EVENT_CALLBACK0*
  - *FWPS_VSWITCH_LIFETIME_EVENT_CALLBACK0*
  - *FWPS_VSWITCH_POLICY_EVENT_CALLBACK0*
  - *FWPS_VSWITCH_PORT_EVENT_CALLBACK0*
  - *FWPS_VSWITCH_RUNTIME_STATE_RESTORE_CALLBACK0*
  - *FWPS_VSWITCH_RUNTIME_STATE_SAVE_CALLBACK0*
- New structures:
  - **FWPS_FILTER2**
  - **FWPS_VSWITCH_EVENT_DISPATCH_TABLE0**
- New enumerations:
  - **FWPS_CONNECTION_REDIRECT_STATE**

- FWPS_FIELDS_EGRESS_VSWITCH_ETHERNET
- FWPS_FIELDS_EGRESS_VSWITCH_TRANSPORT_V4
- FWPS_FIELDS_EGRESS_VSWITCH_TRANSPORT_V6
- FWPS_FIELDS_INBOUND_MAC_FRAME_NATIVE
- FWPS_FIELDS_INGRESS_VSWITCH_ETHERNET
- FWPS_FIELDS_INGRESS_VSWITCH_TRANSPORT_V4
- FWPS_FIELDS_INGRESS_VSWITCH_TRANSPORT_V6
- FWPS_FIELDS_OUTBOUND_MAC_FRAME_NATIVE
- FWPS_VSWITCH_EVENT_TYPE

- Renamed enumerations:
  - FWPS_FIELDS_INBOUND_MAC_FRAME_ETHERNET (was FWPS_FIELDS_INBOUND_MAC_FRAME_802_3)
  - FWPS_FIELDS_OUTBOUND_MAC_FRAME_ETHERNET (was FWPS_FIELDS_OUTBOUND_MAC_FRAME_802_3)

WFP Changes for Windows 7

Article • 12/15/2021

Several changes have been made in the available functions and behavior of the Windows Filtering Platform that begin with Windows 7. Frequently, to take advantage of the new features, you must compile or recompile a callout driver that has the NTDDI_VERSION macro set to NTDDI_WIN7.

- New functions:
  - FwpsAcquireClassifyHandle0
  - FwpsAcquireWritableLayerDataPointer0
  - FwpsApplyModifiedLayerData0
  - FwpsCalloutRegister1
  - FwpsCompleteClassify0
  - FwpsPendClassify0
  - FwpsReleaseClassifyHandle0
  - *classifyFn1*
  - *notifyFn1*
  - FWPS_NET_BUFFER_LIST_NOTIFY_FN0
  - FwpsInjectTransportSendAsync1
  - FwpsNetBufferListAssociateContext0
  - FwpsNetBufferListGetTagForContext0
  - FwpsNetBufferListRemoveContext0
  - FwpsNetBufferListRetrieveContext0
  - FwpsAleEndpointCreateEnumHandle0
  - FwpsAleEndpointDestroyEnumHandle0
  - FwpsAleEndpointEnum0
  - FwpsAleEndpointGetById0
  - FwpsAleEndpointGetSecurityInfo0
  - FwpsAleEndpointSetSecurityInfo0
- New structures and enumerations:
  - FWPS_ALE_ENDPOINT_ENUM_TEMPLATE0
  - FWPS_ALE_ENDPOINT_PROPERTIES0
  - FWPS_BIND_REQUEST0
  - FWPS_CALLOUT1
  - FWPS_CONNECT_REQUEST0
  - FWPS_FIELDS_ALE_BIND_REDIRECT_V4
  - FWPS_FIELDS_ALE_BIND_REDIRECT_V6
  - FWPS_FIELDS_ALE_CONNECT_REDIRECT_V4
  - FWPS_FIELDS_ALE_CONNECT_REDIRECT_V6

- FWPS_FIELDS_ALE_ENDPOINT_CLOSURE_V4
    - FWPS_FIELDS_ALE_ENDPOINT_CLOSURE_V6
    - FWPS_FIELDS_ALE_RESOURCE_RELEASE_V4
    - FWPS_FIELDS_ALE_RESOURCE_RELEASE_V6
    - FWPS_FIELDS_INBOUND_MAC_FRAME_802_3
    - FWPS_FIELDS_KM_AUTHORIZATION
    - FWPS_FIELDS_NAME_RESOLUTION_CACHE_V4
    - FWPS_FIELDS_NAME_RESOLUTION_CACHE_V6
    - FWPS_FIELDS_OUTBOUND_MAC_FRAME_802_3
    - FWPS_FIELDS_STREAM_PACKET_V4
    - FWPS_FIELDS_STREAM_PACKET_V6
    - FWPS_FILTER1
    - FWPS_NET_BUFFER_LIST_EVENT_TYPE0
    - FWPS_TRANSPORT_SEND_PARAMS1
- New documentation topics:
    - Using Bind or Connect Redirection
    - Using Packet Tagging
    - ALE Endpoint Lifetime Management

WFP Changes for Windows Vista SP1 and Windows Server 2008

Article • 12/15/2021

Several changes have been made in the available functions and behavior of the Windows Filtering Platform that begin with Windows Vista with Service Pack 1 (SP1) and Windows Server 2008. Frequently, to take advantage of the new features, you must compile or recompile a callout driver that has the NTDDI_VERSION macro set to NTDDI_WIN6SP1.

- New functions: **FwpsConstructIpHeaderForTransportPacket0** **FwpsReassembleForwardFragmentGroup0**

- New FWPS_STREAM_FLAG_RECEIVE_PUSH flag option that is described in **FwpsStreamInjectAsync0**

- Updated and renamed filtering conditions, listed in Filtering Conditions Available at Each Filtering Layer

- Updated and renamed data field identifiers that were added to FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_*XXX* and FWPS_LAYER_INBOUND_ICMP_ERROR_*XXX* layers, listed in Data Field Identifiers, together with behavior changes

- Additional metadata field identifiers, listed in Metadata Fields and Metadata Fields at Each Filtering Layer

- The following documentation topics are new:
  - Developing IPsec-Compatible Callout Drivers
  - Processing Classify Callouts Asynchronously

- The following topics contain additional updates: Processing Notify Callouts Stream Inspection **FwpsFlowAssociateContext0** **FwpsFlowRemoveContext0** *classifyFn* *notifyFn* **FWPS_CALLOUT0** **FWPS_INCOMING_METADATA_VALUES0**

Callout

Article • 12/15/2021

A *callout* provides functionality that extends the capabilities of the Windows Filtering Platform. A callout consists of a set of callout functions and a GUID key that uniquely identifies the callout. There are several built-in callouts that are included with the Windows Filtering Platform. Additional callouts can be added by using callout drivers.

Callout Driver

Article • 12/15/2021

A *callout driver* is a kernel-mode driver that implements one or more callouts. A callout driver registers its callouts with the filter engine so that the filter engine can call the callout functions for the callout when the computer processes connections or packets.

Callout Function

Article • 12/15/2021

A *callout function* is a function that is implemented by a callout driver that is one of the functions that defines a callout. A callout consists of the following list of callout functions:

- A *notifyFn* function to process notifications.
- A *classifyFn* function to process classifications.
- A *flowDeleteFn* function to process flow deletions (optional).

The filter engine calls a callout's callout functions so that the callout can process the network data.

Filter

Article • 12/15/2021

A *filter* defines several filtering conditions for filtering TCP/IP network data and an action that is to be taken on the data if all the filtering conditions are true. If a filter requires additional processing of the network data, it can specify a callout for the filter's action. If the filtering conditions for such a filter are all true, the filter engine passes the network data to the specified callout for additional processing.

Filter Engine

Article • 12/15/2021

The *filter engine* is a component of the Windows Filtering Platform that stores filters and performs filter arbitration. Filters are added to the filter engine at designated filtering layers so that the filter engine can perform the desired filtering action (permit, drop, or a callout). If a filter in the filter engine specifies a callout for the filter's action, the filter engine calls the callout's *classifyFn* function so that the callout can process the network data.

Filtering Layer

Article • 12/15/2021

A *filtering layer* is a point in the TCP/IP network stack where network data is passed to the filter engine for matching against the current set of filters. Each filtering layer in the network stack is identified by a unique filtering layer identifier.

When a filter is added to the filter engine, it is added at a designated filtering layer where it will filter the network data. Specific data fields are made available at each filtering layer for processing by the filters that have been added to the filter engine at that layer. If the filter engine passes the network data to a callout for additional processing, it includes these data fields and any metadata that is available at that filtering layer.

Run-time Filtering Layer Identifiers (FWPS_*XXX*) are used by kernel-mode callout drivers. Management Filtering Layer Identifiers (FWPM_*XXX*) are used by **Fwpm*Xxx*** functions that interact with the Base Filtering Engine (BFE) from either user mode or kernel mode (for example, **FwpmFilterAdd0**).

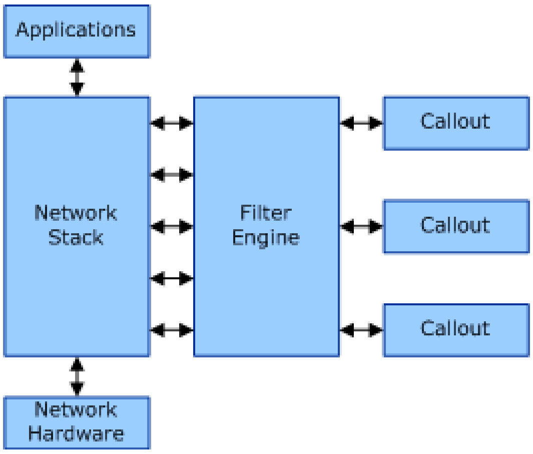
The FWPS data types are smaller than their FWPM counterparts: the FWPM filtering layer identifiers are GUIDs (128 bits), whereas the FWPS filtering layer identifiers are **LUIDs**(64 bits). The smaller size for FWPS data types improves system performance because integer comparisons are faster than GUID comparisons for real-time traffic, and the kernel memory handles FWPS types more efficiently.

Windows Filtering Platform Architecture Overview

Article • 12/15/2021

This section provides a brief overview of the Windows Filtering Platform architecture. For a more thorough discussion of the Windows Filtering Platform architecture, see the Windows Filtering Platform documentation in the Microsoft Windows SDK.

The following figure shows the basic architecture of the Windows Filtering Platform.



The filter engine is the core of the Windows Filtering Platform. The filter engine performs all the filtering operations on the TCP/IP-based network data. At key points in the TCP/IP stack there are filtering layers where network data is passed to the filter engine for processing. If the filtering conditions for a filter of the filtering layer are all true, the filter engine applies the filter's action.

Callout drivers provide additional filtering functionality by registering one or more callouts with the filter engine. Filters in the filter engine can specify a callout for the filter's action. In this case, the filter engine passes the network data to the specified callout for additional processing.

The Windows Filtering Platform includes several built-in callouts. See Built-in Callout Identifiers for a description of each of these callouts.

Callout Driver Operations Topics

Article • 12/15/2021

This section discusses typical callout driver operations and includes the following topics:

Initializing a Callout Driver

Processing Notify Callouts

Processing Classify Callouts

Processing Flow Delete Callouts

Using Packet Tagging

Using Layer 2 Filtering

Using Proxied Connections Tracking

Using Virtual Switch Filtering

Unloading a Callout Driver

In addition to these operations, callout drivers can perform other Windows Filtering Platform management tasks, such as adding filters to the base filtering engine. For more information about the tasks that a callout driver can perform, see Calling Other Windows Filtering Platform Functions.

Initializing a Callout Driver

Article • 12/15/2021

A callout driver initializes itself within its **DriverEntry** function. The main initialization tasks are as follows:

- Specifying an Unload Function
- Creating a Device Object
- Registering Callouts with the Filter Engine

Specifying an Unload Function

Article • 12/15/2021

A callout driver must provide an unload function. The operating system calls this function when the callout driver is unloaded from the system. A callout driver's unload function must guarantee that the callout driver's callouts are unregistered from the filter engine before the callout driver is unloaded from system memory. A callout driver cannot be unloaded from the system if it does not provide an unload function.

How a callout driver specifies an unload function depends on whether the callout driver is based on the Windows Driver Model (WDM) or the Windows Driver Frameworks (WDF).

WDM-Based Callout Drivers

If a callout driver is based on WDM, it specifies an **Unload** function in its **DriverEntry** function. For example:

C++

```
VOID
 Unload(
    IN PDRIVER_OBJECT DriverObject
    );

NTSTATUS
 DriverEntry(
    IN PDRIVER_OBJECT DriverObject,
    IN PUNICODE_STRING RegistryPath
    )
{
  ...

  // Specify the callout driver's Unload function
 DriverObject->DriverUnload = Unload;

  ...
}
```

WDF-Based Callout Drivers

If a callout driver is based on WDF, it specifies an *EvtDriverUnload* function in its **DriverEntry** function. For example:

C++

```
VOID
 Unload(
    IN WDFDRIVER Driver
    );

NTSTATUS
 DriverEntry(
    IN PDRIVER_OBJECT DriverObject,
    IN PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS status;
  WDF_DRIVER_CONFIG config;
  WDFDRIVER driver;

  ...

  // Initialize the driver config structure
  WDF_DRIVER_CONFIG_INIT(&config, NULL);

  // Indicate that this is a non-PNP driver
 config.DriverInitFlags = WdfDriverInitNonPnpDriver;

  // Specify the callout driver's Unload function
 config.EvtDriverUnload = Unload;

  // Create a WDFDRIVER object
 status =
 WdfDriverCreate(
 DriverObject,
 RegistryPath,
      NULL,
      &config,
      &driver
      );

  ...

 return status;
}
```

For information about how to implement a callout driver's unload function, see Unloading a Callout Driver.

Creating a Device Object (Windows Filtering Platform)

Article • 12/15/2021

A callout driver must create a device object before it can register its callouts with the filter engine. How a callout driver creates a device object depends on whether the callout driver is based on the Windows Driver Model (WDM) or the Windows Driver Frameworks (WDF).

WDM-Based Callout Drivers

If a callout driver is based on WDM, it creates a device object by calling the IoCreateDevice function. For example:

```C++
PDEVICE_OBJECT deviceObject;

NTSTATUS
 DriverEntry(
    IN PDRIVER_OBJECT DriverObject,
    IN PUNICODE_STRING RegistryPath
    )
{
  NTSTATUS status;

  ...

  // Create a device object
 status =
 IoCreateDevice(
 DriverObject,
      0,
      NULL,
      FILE_DEVICE_UNKNOWN,
      FILE_DEVICE_SECURE_OPEN,
      FALSE,
      &deviceObject
      );

  ...

 return status;
}
```

WDF-Based Callout Drivers

If a callout driver is based on WDF, it creates a framework device object by calling the WdfDeviceCreate function. To register its callouts with the filter engine, a WDF-based callout driver must obtain a pointer to the WDM device object that is associated with the framework device object. A WDF-based callout driver obtains a pointer to this WDM device object by calling the WdfDeviceWdmGetDeviceObject function. For example:

C++

```
WDFDEVICE wdfDevice;

NTSTATUS
 DriverEntry(
    IN PDRIVER_OBJECT DriverObject,
    IN PUNICODE_STRING RegistryPath
    )
{
  WDFDRIVER driver;
  PWDFDEVICE_INIT deviceInit;
  PDEVICE_OBJECT deviceObject;
  NTSTATUS status;

  ...

  // Allocate a device initialization structure
 deviceInit =
 WdfControlDeviceInitAllocate(
    driver;
    &SDDL_DEVOBJ_KERNEL_ONLY
    );

  // Set the device characteristics
 WdfDeviceInitSetCharacteristics(
    deviceInit,
    FILE_DEVICE_SECURE_OPEN,
    FALSE
    );

  // Create a framework device object
 status =
 WdfDeviceCreate(
    &deviceInit,
    WDF_NO_OBJECT_ATTRIBUTES,
    &wdfDevice
    );

  // Check status
 if (status == STATUS_SUCCESS) {

    // Initialization of the framework device object is complete
    WdfControlFinishInitializing(
      wdfDevice
    );

    // Get the associated WDM device object
    deviceObject = WdfDeviceWdmGetDeviceObject(wdfDevice);
  }

  ...

 return status;
}
```

Registering Callouts with the Filter Engine

Article • 12/15/2021

After a callout driver has created a device object, it can then register its callouts with the filter engine. A callout driver can register its callouts with the filter engine at any time, even if the filter engine is currently not running. To register a callout with the filter engine, a callout driver calls the **FwpsCalloutRegister0** function. For example:

```C++
// Prototypes for the callout's callout functions
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    IN OUT FWPS_CLASSIFY_OUT0  *classifyOut
    );

NTSTATUS NTAPI
 NotifyFn(
 IN FWPS_CALLOUT_NOTIFY_TYPE notifyType,
    IN const GUID  *filterKey,
    IN const FWPS_FILTER0  *filter
    );

VOID NTAPI
 FlowDeleteFn(
    IN UINT16  layerId,
    IN UINT32  calloutId,
    IN UINT64  flowContext
    );

// Callout registration structure
const FWPS_CALLOUT0 Callout =
{
 { ... }, // GUID key identifying the callout
  0,       // Callout-specific flags (none set here)
 ClassifyFn,
 NotifyFn,
 FlowDeleteFn
};

// Variable for the run-time callout identifier
UINT32 CalloutId;
```

```
NTSTATUS
 DriverEntry(
    IN PDRIVER_OBJECT DriverObject,
    IN PUNICODE_STRING RegistryPath
    )
{
  PDEVICE_OBJECT deviceObject;
  NTSTATUS status;

  ...

 status =
 FwpsCalloutRegister0(
 deviceObject,
      &Callout,
      &CalloutId
      );

  ...

 return status;
}
```

If the call to the FwpsCalloutRegister0 function is successful, the variable pointed to by the last parameter contains the run-time identifier for the callout. This run-time identifier corresponds to the GUID that was specified for the callout key.

A single callout driver can implement more than one callout. If a callout driver implements more than one callout, it calls the FwpsCalloutRegister0 function one time for each callout that it supports to register each callout with the filter engine.

Processing Notify Callouts

Article • 12/15/2021

The filter engine calls a callout's *notifyFn* callout function to notify the callout driver about events that are associated with the callout.

Filter Addition

When a filter that specifies a callout for the filter's action is added to the filter engine, the filter engine calls the callout's *notifyFn* callout function, passing FWPS_CALLOUT_NOTIFY_ADD_FILTER in the *notifyType* parameter.

A callout driver can register a callout with the filter engine after filters that specify the callout for the filter's action have already been added to the filter engine. In this situation, the filter engine does not call the callout's *notifyFn* callout function to notify the callout about any of the existing filters.

The filter engine only calls the callout's *notifyFn* callout function to notify the callout when new filters that specify the callout for the filter's action are added to the filter engine. In this situation, a callout's *notifyFn* callout function might not get called for every filter in the filter engine that specifies the callout for the filter's action.

If a callout driver registers a callout after the filter engine is started and the callout must receive information about every filter in the filter engine that specifies the callout for the filter's action, the callout driver must call the appropriate management functions to enumerate all the filters in the filter engine. The callout driver must sort through the resulting list of all the filters to find those filters that specify the callout for the filter's action. See Calling Other Windows Filtering Platform Functions for more information about calling these functions.

Filter Deletion

When a filter that specifies a callout for the filter's action is deleted from the filter engine, the filter engine calls the callout's *notifyFn* callout function and passes FWPS_CALLOUT_NOTIFY_DELETE_FILTER in the *notifyType* parameter and **NULL** in the *filterKey* parameter. The filter engine calls the callout's *notifyFn* callout function for every deleted filter in the filter engine that specifies the callout for the filter's action. This includes any filters that were added to the filter engine before the callout driver registered the callout with the filter engine. Therefore, a callout might receive filter delete notifications for filters for which it did not receive filter add notifications.

If the callout's *notifyFn* callout function does not recognize the kind of notification that is passed in the *notifyType* parameter, it should ignore the notification and return STATUS_SUCCESS.

A callout driver can specify a context to be associated with a filter when the filter is added to the filter engine. Such a context is opaque to the filter engine. The callout's *classifyFn* callout function can use this context to save state information for the next time that it is called by the filter engine. When the filter is deleted from the filter engine, the callout driver performs any necessary cleanup of the context.

For example:

```C++
// Context structure to be associated with the filters
typedef struct FILTER_CONTEXT_ {
  .
  .  // Driver-specific content
  .
} FILTER_CONTEXT, *PFILTER_CONTEXT;

// Memory pool tag for filter context structures
#define FILTER_CONTEXT_POOL_TAG 'fcpt'

// notifyFn callout function
NTSTATUS NTAPI
 NotifyFn(
    IN FWPS_CALLOUT_NOTIFY_TYPE  notifyType,
    IN const GUID  *filterKey,
    IN const FWPS_FILTER0  *filter
    )
{
  PFILTER_CONTEXT context;

 ASSERT(filter != NULL);

  // Switch on the type of notification
 switch(notifyType) {

    // A filter is being added to the filter engine
 case FWPS_CALLOUT_NOTIFY_ADD_FILTER:

      // Allocate the filter context structure
 context =
        (PFILTER_CONTEXT)ExAllocatePoolWithTag(
 NonPagedPool,
 sizeof(FILTER_CONTEXT),
          FILTER_CONTEXT_POOL_TAG
          );

      // Check the result of the memory allocation
 if (context == NULL) {
        // Return error
 return STATUS_INSUFFICIENT_RESOURCES;
      }

      // Initialize the filter context structure
      ...

      // Associate the filter context structure with the filter
 filter->context = (UINT64)context;

 break;

    // A filter is being removed from the filter engine
 case FWPS_CALLOUT_NOTIFY_DELETE_FILTER:

      // Get the filter context structure from the filter
 context = (PFILTER_CONTEXT)filter->context;

 // Check whether the filter has a context
 if (context) {

        // Cleanup the filter context structure
        ...

        // Free the memory for the filter context structure
 ExFreePoolWithTag(
 context,
         FILTER_CONTEXT_POOL_TAG
         );

      }
 break;

    // Unknown notification
 default:

      // Do nothing
 break;
  }

 return STATUS_SUCCESS;
}
```

Processing Classify Callouts

Article • 12/15/2021

The filter engine calls a callout's *classifyFn* callout function when there is network data to be processed by the callout. This occurs when all the filtering conditions are true for a filter that specifies the callout for the filter's action. If such a filter has no filtering conditions, the filter engine always calls the callout's *classifyFn* callout function.

The filter engine passes several different data items to a callout's *classifyFn* callout function. These data items include fixed data values, metadata values, raw network data, filter information, and any flow context. The particular data items that the filter engine passes to the callout depend on the specific filtering layer and the conditions under which *classifyFn* is called. A *classifyFn* function can use any combination of these data items to make its filtering decisions.

The implementation of a callout's *classifyFn* callout function depends on what the callout is designed to do. The following sections provide examples of some the more typical functions of a callout:

Using a Callout for Deep Inspection

Using a Callout for Deep Inspection of Stream Data

Inspecting Packet and Stream Data

Modifying Stream Data

Data Logging

Associating Context with a Data Flow

Processing Classify Callouts Asynchronously

Using Bind or Connect Redirection

ALE Endpoint Lifetime Management

Using Packet Tagging

The actual implementation of a particular callout's *classifyFn* callout function can be based on a combination of these examples.

For callouts that process data at a filtering layer that supports data flows, the callout's *classifyFn* callout function can associate a context with each of the data flows. The *classifyFn* function can use this context to save state information for the next time that it is called by the filter engine for that data flow. For more information about how a callout function can associate a context with a data flow, see Associating Context with a Data Flow.

WFP supports asynchronous processing of the *classifyFn* callout function. For more information about asynchronous processing, see Processing Classify Callouts Asynchronously.

Using a Callout for Deep Inspection

Article • 12/15/2021

When a callout is performing deep inspection, its classifyFn callout function can inspect any combination of the fixed data fields, the metadata fields, and any raw packet data that is passed to it, and any relevant data that has been stored in a context associated with the filter or the data flow.

For example:

```C++
// classifyFn callout function
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    IN OUT FWPS_CLASSIFY_OUT  *classifyOut
    )
{
  PNET_BUFFER_LIST rawData;
  ...

  // Test for the FWPS_RIGHT_ACTION_WRITE flag to check the rights
  // for this callout to return an action. If this flag is not set,
  // a callout can still return a BLOCK action in order to VETO a
  // PERMIT action that was returned by a previous filter. In this
  // example the function just exits if the flag is not set.
 if (!(classifyOut->rights & FWPS_RIGHT_ACTION_WRITE))
  {
    // Return without specifying an action
 return;
  }

  // Get the data fields from inFixedValues
  ...

  // Get any metadata fields from inMetaValues
  ...

  // Get the pointer to the raw data
 rawData = (PNET_BUFFER_LIST)layerData;

  // Get any filter context data from filter->context
  ...

  // Get any flow context data from flowContext
  ...

  // Inspect the various data sources to determine
  // the action to be taken on the data
  ...

  // If the data should be permitted...
 if (...) {

    // Set the action to permit the data
 classifyOut->actionType = FWP_ACTION_PERMIT;

    // Check whether the FWPS_RIGHT_ACTION_WRITE flag should be cleared
 if (filter->flags & FWPS_FILTER_FLAG_CLEAR_ACTION_RIGHT)
    {
       // Clear the FWPS_RIGHT_ACTION_WRITE flag
 classifyOut->rights &= ~FWPS_RIGHT_ACTION_WRITE;
    }

 return;
  }

  ...

  // If the data should be blocked...
 if (...) {

    // Set the action to block the data
 classifyOut->actionType = FWP_ACTION_BLOCK;

    // Clear the FWPS_RIGHT_ACTION_WRITE flag
 classifyOut->rights &= ~FWPS_RIGHT_ACTION_WRITE;

 return;
  }

  ...

  // If the decision to permit or block should be passed
  // to the next filter in the filter engine...
 if (...) {

    // Set the action to continue with the next filter
 classifyOut->actionType = FWP_ACTION_CONTINUE;

 return;
  }

  ...
}
```

The value in *filter->action.type* determines which actions the callout's classifyFn callout function should return in the **actionType** member of the structure pointed to by the *classifyOut* parameter. For more information about these actions, see the **FWPS_ACTION0** structure.

If a callout must perform additional processing of packet data outside its classifyFn callout function before it can determine whether the data should be permitted or blocked, it must pend the packet data until the processing of the data is completed. For information about how to pend packet data, see Types of Callouts and **FwpsPendOperation0**.

At some filtering layers, the *layerData* parameter that is passed by the filter engine to a callout's classifyFn callout function is **NULL**.

For information about how to perform deep inspection of stream data, see Using a Callout for Deep Inspection of Stream Data.

Using a Callout for Deep Inspection of Stream Data

Article • 12/15/2021

When a callout inspects stream data, its classifyFn callout function can inspect any combination of the fixed data fields, the metadata fields, and the raw stream data that is passed to it, and any relevant data that has been stored in a context associated with the filter or the data flow.

For example:

```C++
// classifyFn callout function
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    IN OUT FWPS_CLASSIFY_OUT  *classifyOut
    )
{
  FWPS_STREAM_CALLOUT_IO_PACKET0 *ioPacket;
  FWPS_STREAM_BUFFER0 *dataStream;
  UINT32 bytesRequired;
  SIZE_T bytesToPermit;
  SIZE_T bytesToBlock;
  ...

  // Get a pointer to the stream callout I/O packet
 ioPacket = (FWPS_STREAM_CALLOUT_IO_PACKET0 *)layerData;

  // Get the data fields from inFixedValues
  ...

  // Get any metadata fields from inMetaValues
  ...

  // Get the pointer to the data stream
 dataStream = ioPacket->dataStream;

  // Get any filter context data from filter->context
  ...

  // Get any flow context data from flowContext
  ...
  // Inspect the various data sources to determine
  // the action to be taken on the data
  ...

  // If more stream data is required to make a determination...
 if (...) {

    // Let the filter engine know how many more bytes are needed
 ioPacket->streamAction = FWPS_STREAM_ACTION_NEED_MORE_DATA;
 ioPacket->countBytesRequired = bytesRequired;
 ioPacket->countBytesEnforced = 0;

    // Set the action to continue to the next filter
 classifyOut->actionType = FWP_ACTION_CONTINUE;

 return;
  }
  ...

  // If some or all of the data should be permitted...
 if (...) {

    // No stream-specific action is required
 ioPacket->streamAction = FWPS_STREAM_ACTION_NONE;

    // Let the filter engine know how many of the leading bytes
    // in the stream should be permitted
 ioPacket->countBytesRequired = 0;
 ioPacket->countBytesEnforced = bytesToPermit;

    // Set the action to permit the data
 classifyOut->actionType = FWP_ACTION_PERMIT;

 return;
  }

  ...

  // If some or all of the data should be blocked...
 if (...) {

    // No stream-specific action is required
 ioPacket->streamAction = FWPS_STREAM_ACTION_NONE;

    // Let the filter engine know how many of the leading bytes
    // in the stream should be blocked
 ioPacket->countBytesRequired = 0;
 ioPacket->countBytesEnforced = bytesToBlock;

    // Set the action to block the data
 classifyOut->actionType = FWP_ACTION_BLOCK;

 return;
  }
```

```
  ...

  // If the decision to permit or block should be passed
  // to the next filter in the filter engine...
 if (...) {

    // No stream-specific action is required
 ioPacket->streamAction = FWPS_STREAM_ACTION_NONE;

    // No bytes are affected by this callout
 ioPacket->countBytesRequired = 0;
 ioPacket->countBytesEnforced = 0;

 return;
  }

  ...
}
```

The value in *filter->action.type* determines which actions the callout's classifyFn callout function should return in the **actionType** member of the structure pointed to by the *classifyOut* parameter. For more information about these actions, see the **FWPS_ACTION0** structure.

For more information about packet and stream data inspection, see Inspecting Packet and Stream Data.

Packet Inspection Points

Article • 12/15/2021

Incoming packets

Incoming packets that are destined for an address that is assigned to the receiving computer (local host traffic) traverse up WFP layers in the following order:

IP Packet (Network Layer)
All IP packets, including IP packet fragments, are available for inspection at this layer. However, when packets are IPsec-protected, deep content inspection or modification cannot be performed at this layer because the packets are not yet authenticated or decrypted.

Transport Layer
All stand-alone or fully reassembled packets are available for inspection at this layer. IPsec-protected packets have been authenticated or decrypted.

Application Layer Enforcement (ALE) Receive or Accept
The very first packet that arrives at a local endpoint is indicated at this layer. For example, an arriving TCP synchronize (SYN) segment or the first UDP message that is associated with a UDP flow would be indicated. Packets that are required to re-authorize a connection, for example, after a firewall policy change, are also indicated at this layer, and the ALE reauthorization flag will be set.

Datagram Data or Stream
UDP messages and non-ICMP error messages are indicated at the datagram data layer. This layer allows for inspecting network data on a per datagram basis. At the datagram layer, the network data is bidirectional. TCP data flows (data streams only) are available for inspection at the stream layer.

Outgoing packets

Outgoing packets that originate from an address that is assigned to the sending computer (local host sourced traffic) traverse down the following WFP layers:

ALE Connect
TCP connection requests (made before the SYN segment is generated) and the first UDP message that is sent to a remote endpoint are indicated at this layer.

Datagram Data or Stream

UDP messages and non-ICMP error messages are indicated at the datagram data layer. This layer allows for inspecting network data on a per datagram basis. At the datagram layer, the network data is bidirectional. TCP data flows (data streams only) are available for inspection at the stream layer.

Transport and ICMP Error
The transport filtering layer is located in the send path just after a sent packet has been passed to the network layer for processing but before any network layer processing takes place. This filtering layer is located at the top of the network layer instead of at the bottom of the transport layer so that any packets that are sent by third-party transports or as raw packets are filtered at this layer.

The ICMP Error filtering layer is located in the send path for inspecting received ICMP error messages for the transport protocol.

IP Packet
IP packet fragments are not indicated; inspection of outgoing IP fragments is currently unavailable.

IP packets or fragments that do not originate from, or are not destined for, an address that is assigned to the local computer are available for inspection at the forwarding layer. For example, if a packet that is destined for a local client is modified to have a nonlocal destination address and then is injected into the receive path, it will be injected into the forwarding layer. Similarly, if a packet that originates from a local source address is modified to have a nonlocal source address, it will be delivered to the forwarding layer after it is injected into the send path.

WFP Layer Requirements and Restrictions

Article • 12/15/2021

The following requirements and restrictions apply to WFP layers.

Forwarding Layer
An IP packet will be delivered to the forwarding layer if IP forwarding is enabled for a packet that originates from, or is destined for, an address that is assigned to the computer and the packet is sent or received on a different interface than the interface on which the local address is assigned. By default, IP forwarding is disabled and can be enabled by using the **netsh interface ipv4 set interface** command for IPv4 forwarding or the **netsh interface ipv6 set interface** command for IPv6 forwarding.

The forwarding layer can forward each received fragment as it arrives or hold the fragments of an IP payload until all fragments have arrived and then forward them. This is known as *fragment grouping*. When fragment grouping is disabled (it is disabled by default), forwarded IP packet fragments are indicated to WFP one time. When fragment grouping is enabled, a fragment is indicated to WFP two times--first as the fragment itself, and again inside a fragment group that is described by a NET_BUFFER_LIST chain. WFP sets the **FWP_CONDITION_FLAG_IS_FRAGMENT_GROUP** flag when it indicates fragment groups to forwarding layer callouts. You can enable fragment grouping by using the **netsh interface {ipv4|ipv6} set global groupforwardedfragments=enabled** command. Fragment grouping is different than reassembly, which is the reconstruction of the original IP packet at the destination host.

The NET_BUFFER_LIST structure that is indicated at the forwarding layer can describe a full IP packet, an IP packet fragment, or an IP packet fragment group. While an IP packet fragment traverses the forwarding layer, it will be indicated two times to the callout: first as a fragment, and again, as a fragment inside a fragment group.

When a fragment group is indicated, the **FWP_CONDITION_FLAG_IS_FRAGMENT_GROUP** flag is passed as an incoming value to the callout driver's *classifyFn* callout function. In this case, the NET_BUFFER_LIST structure pointed to by the *NetBufferList* parameter is the first node of a **NET_BUFFER_LIST** chain with each **NET_BUFFER_LIST** describing a packet fragment.

A forward injected packet will not be presented to any WFP layer. The injected packet can be indicated to the callout driver again. To prevent infinite looping, the driver should first call the FwpsQueryPacketInjectionState0 function before it continues with a call to the *classifyFn* callout function, and the driver should permit packets that have the injection state FWPS_PACKET_INJECTION_STATE set to **FWPS_PACKET_INJECTED_BY_SELF** or **FWPS_PACKET_PREVIOUSLY_INJECTED_BY_SELF** to pass through unaltered.

You can use the following command to view the current "Group Forwarded Fragments" setting for the system: **netsh interface {ipv4|ipv6} show global**.

Network Layer
IP packet fragments, which are indicated only for incoming paths, are indicated at three points at this layer: first as an IP packet, again as an IP fragment, and a third time as part of a reassembled IP packet. WFP sets the **FWP_CONDITION_FLAG_IS_FRAGMENT** flag when it indicates fragments to network layer callouts.

For example, if a single IP packet is divided into four fragments, the indications for this packet occur as follows:

1. One indication for each "original" IP packet (4 classifications, or calls to the callout's classify function)
2. One indication for each "original fragment" (4 classifications)
3. One indication for the final reassembled IP packet (1 classification)

When adding filtering conditions, **FWP_MATCH_FLAGS_NONE_SET** can be used together with the **FWP_CONDITION_FLAG_IS_FRAGMENT** flag to avoid the second indication(s). These condition flags are meant to prevent classifications the callout driver does not care about. If the callout has to inspect only full packets (those that have not been fragmented and reassembled), it has to parse the IP header to avoid processing fragments that are indicated as IP packets. A callout might do the following steps to achieve this:

1. Skip the first indication(s) by checking if the More Fragments (MF) flag is set and/or the Fragment Offset field is not 0.
2. Write a filter that allows all classifications where **FWP_CONDITION_FLAG_IS_FRAGMENT** is set.
3. Perform whatever processing is needed on the reassembled packet.

Alternatively, the callout can inspect packets at the transport layer.

Transport Layer and ALE
To be able to coexist with IPsec processing, callouts that inspect packets at the incoming transport layer must also register at the ALE receive and accept layer. Such a callout can inspect/modify most of the traffic at the transport layer, but it must also permit packets that are assigned to the ALE receive/accept layer. Such a callout must also inspect or modify the packets from the ALE layer. WFP sets the

FWPS_METADATA_FIELD_ALE_CLASSIFY_REQUIRED metadata flag when it indicates to the transport layer those packets that require ALE inspection. IPsec processing is deferred until those packets that create the initial "connection" and those that are required to re-authorize the connection reach the ALE layer.

Transport layer and ALE layer callouts must register themselves at a sublayer that is of lower weight than the universal sublayer. The built-in IPsec/ALE enforcement callouts reside at the universal sublayer.

The following table shows packet types that can be indicated at ALE layers. Be aware that some ALE layers do not always have a packet associated with their indication.

ALE layer	TCP packets	UDP packets
Bind (resource assignment)	not applicable	not applicable
Connect	no packet	first UDP packet (outgoing)
Receive/Accept	SYN (incoming)	first UDP packet (incoming)
Flow Established	final ACK (incoming & outgoing)	first UDP packet (incoming & outgoing)

Packet Indication Format

Article • 12/15/2021

Network data is indicated in WFP as NDIS net buffer lists (NET_BUFFER_LIST). The **Next** member of the **NET_BUFFER_LIST** structure can be used to describe a *chain* of net buffer lists. WFP only indicates a single net buffer list to callouts (that is, netBufferList->Next == **NULL**), except for the following cases:

- WFP can indicate net buffer list chains to callouts from the Stream layer.
- WFP indicates net buffer list chains to callouts when it classifies IP packet fragment groups in the forward path to callouts. Each net buffer list inside the chain describes a single fragment.

Although a net buffer list can describe a whole packet, for different types of layers, WFP indicates net buffer lists to callouts at different offsets from the beginning of IP header. For example, at the incoming network layer, the net buffer list starts after the IP header, while at the incoming transport layer, the net buffer list starts after the transport header. IP and transport headers are always described by the first NET_BUFFER structure inside a net buffer list.

Offsets into the net buffer lists are indicated to callouts by using the **ipHeaderSize** and **transportHeaderSize** members of the FWPS_INCOMING_METADATA_VALUES0 structure. Callouts can use the NDIS functions NdisRetreatNetBufferDataStart and NdisAdvanceNetBufferDataStart to adjust the offset of the indicated net buffer lists. However in this case, the callout must undo the offset adjustment before it returns from the *classifyFn* function.

In a call to the *classifyFn* function for outgoing data, a NET_BUFFER_LIST can contain more than one NET_BUFFER structure, each of which describes an IP packet. If some packets (for example, net buffers) in a net buffer list are acceptable, but others are not, a callout driver must do the following:

1. Clone and block the whole net buffer list.
2. Build a new net buffer list that describes the acceptable subset of net buffers.
3. Inject the new net buffer list back into the send path.

Alternatively, the callout can unlink the unwanted net buffers from the net buffer list and inject the altered net buffer list back into the send path. However, in this case the callout driver must undo this modification to the cloned net buffer list before it calls the

FwpsFreeCloneNetBufferList0 function. The callout driver must also save the original net buffer linkage information as part of its state data.

For more information about data offsets that are used by WFP, see Data Offset Positions.

Note Callouts that work with decrypted IPSec ESP packets must use the data length of the **NET_BUFFER** structure instead of MDL data to determine the packet length. To obtain the data length, use the **NET_BUFFER_DATA_LENGTH** macro. For more information, see Developing IPsec-Compatible Callout Drivers.

Types of Callouts

Article • 12/15/2021

The following types of callouts can be used with WFP:

Inline Inspection Callout
This type of callout always returns **FWP_ACTION_CONTINUE** from the *classifyFn* function and does not modify the network traffic in any way. A callout that collects network statistics is an example of this type of callout.

For this type of callout, the filter action type (specified by the **Type** member of the **FWPS_ACTION0** structure) should be set to **FWP_ACTION_CALLOUT_INSPECTION**.

Out-of-band Inspection Callout
This type of callout does not modify network traffic. Instead, it defers any inspection to be done outside the *classifyFn* function by "pending" the indicated data and then reinjecting the pended data back into the TCP/IP stack with one of the packet injection functions. Pending is implemented by first cloning the indicated data, followed by returning **FWP_ACTION_BLOCK** from the *classifyFn* function that has the **FWPS_CLASSIFY_OUT_FLAG_ABSORB** bit set.

Inline Modification Callout
This type of callout modifies network traffic by first making a clone of the indicated data, then modifying the clone, and finally injecting the modified clone back into the TCP/IP stack from the *classifyFn* function. This type of callout also returns **FWP_ACTION_BLOCK** from the *classifyFn* function that has the **FWPS_CLASSIFY_OUT_FLAG_ABSORB** bit set.

The filter action type for this type of callout should be set to **FWP_ACTION_CALLOUT_TERMINATING**.

Out-of-band Modification Callout
This type of callout first references the indicated packet by using the **FwpsReferenceNetBufferList0** function that has the *intentToModify* parameter set to **TRUE**. The callout then returns **FWP_ACTION_BLOCK** with the **FWPS_CLASSIFY_OUT_FLAG_ABSORB** bit set from the *classifyFn* function. When the packet is ready to be modified outside *classifyFn*, the callout clones the referenced packet (as soon as it is cloned, the original packet can then be dereferenced). The callout then modifies the clone and injects the modified packet back into the TCP/IP stack.

The filter action type for this type of callout should be set to **FWP_ACTION_CALLOUT_TERMINATING**.

Redirection Callout

For more information about this type of callout, see Using Bind or Connect Redirection.

There are two types of redirection callouts:

- A bind redirection callout allows the callout driver to modify the local address and local port of a socket.
- A connect redirection callout allows the callout driver to modify the remote address and remote port of a connection.

The filter action type for this type of callout should be set to **FWP_ACTION_PERMIT**.

For more information about **FWPS_CLASSIFY_OUT_FLAG_ABSORB**, see **FWPS_CLASSIFY_OUT0**. This flag is not valid at any WFP discard layer. Returning **FWP_ACTION_BLOCK** with the **FWPS_CLASSIFY_OUT_FLAG_ABSORB** flag set from the *classifyFn* function causes the packet to be silently discarded, in such a way that the packet will not hit any of the WFP discard layers, nor will it cause audit events to be generated.

Although cloned net buffer lists can be modified, for example, by adding or removing net buffers or MDLs, or both, callouts must undo such modifications before they call the **FwpsFreeCloneNetBufferList0** function.

To coexist with other callouts that perform packet inspection, packet modification, or connection redirection, before a packet is pended with the reference/clone-drop-reinject mechanism, a callout must "hard"-drop the original packet by clearing the **FWPS_RIGHT_ACTION_WRITE** flag in the **rights** member of the **FWPS_CLASSIFY_OUT0** structure returned by the *classifyFn* function. If the **FWPS_RIGHT_ACTION_WRITE** flag is set when *classifyFn* is called (which means that the packet could be pended and later reinjected or modified), the callout must not pend the indication and should not change the current action type; and it must wait for a higher-weight callout to inject the clone that might be modified.

The **FWPS_RIGHT_ACTION_WRITE** flag should be set whenever a callout pends a classification. Your callout driver should test for the **FWPS_RIGHT_ACTION_WRITE** flag to check the rights for your callout to return an action. If this flag is not set, your callout can still return a **FWP_ACTION_BLOCK** action in order to veto a **FWP_ACTION_PERMIT** action that was returned by a previous callout. In the example shown in Using a Callout for Deep Inspection, the function just exits if the flag is not set.

The **FwpsPendOperation0** function is used to pend packets that originate from the **FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT**_*XXX*,

FWPM_LAYER_ALE_AUTH_LISTEN_*XXX*, or **FWPM_LAYER_ALE_AUTH_CONNECT_***XXX* management filtering layers.

The **FwpsPendClassify0** function is used to pend packets that originate from the following run-time filtering layers:

FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V4 FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V6 FWPS_LAYER_ALE_CONNECT_REDIRECT_V4 FWPS_LAYER_ALE_CONNECT_REDIRECT_V6 FWPS_LAYER_ALE_BIND_REDIRECT_V4 FWPS_LAYER_ALE_BIND_REDIRECT_V6

Packet Injection Functions

Article • 12/15/2021

A callout driver can call the following WFP functions to inject pended or modified packet data into the TCP/IP stack. The applicable layers from which data can be injected, together with possible destinations, are listed in the following table.

Injection function	Applicable layer	Destination
FwpsInjectForwardAsync0	network layer	the forwarding data path
FwpsInjectNetworkReceiveAsync0	network layer	the receive data path
FwpsInjectNetworkSendAsync0	network layer	the send data path
FwpsInjectTransportReceiveAsync0	packet data from the transport, datagram data, ICMP error, or ALE layers	the receive data path
FwpsInjectTransportSendAsync0	packet data from the transport, datagram data, ICMP error, or ALE layers	the send data path
FwpsStreamInjectAsync0	TCP data segments	a data stream

In addition, the FwpsQueryPacketInjectionState0 function is used to inspect the injection history of packet data.

Cross-layer injection is enabled if the callout can supply all needed information that is required by the injection function, and the net buffer list has the format expected by the injection function. For example, a callout can capture a packet at the forward path, modify its destination address to that of the local computer, and call **FwpsInjectTransportReceiveAsync0** to redirect the packet into the local computer's TCP/IP stack.

Except for the stream (TCP data) injection, injected incoming packets reenter from the "bottom" of the stack and WFP layers, while injected outgoing packets reenter from the "top" of the stack and WFP layers. For example, a UDP packet injected from the incoming datagram data layer will reenter the stack and traverse the network layer, the transport layer, the ALE receive or accept layer (optional), and back into the datagram data layer. Another UDP packet injected from the outgoing network layer will reenter the stack and traverse the ALE (optional), datagram data, and transport layers, and back to the network layer.

FwpsInjectTransportReceiveAsync0 automatically bypasses IPsec processing for the reinjected packet because it had previously gone through IPsec verification.

A packet injected by a WFP callout driver will be re-indicated to the callout except in the cases in which modification to the packet causes it to miss the original filter conditions. WFP provides the **FwpsQueryPacketInjectionState0** function for callouts to query whether the packet was injected (or injected earlier) by the callout. To prevent infinite looping, callouts should permit self-injected packets.

Callouts must adjust the IP or transport layer checksum, or both, after they modify an IP packet. A callout can set the checksum to 0 for UDP over IPv4 packets. To be compatible with transport layer checksum offload, and to adjust the full checksum versus pseudo checksum calculations accordingly, a callout can use the following logic:

C++

```
NDIS_TCP_IP_CHECKSUM_PACKET_INFO ChecksumInfo;
 ChecksumInfo.Value =
 (ULONG) (ULONG_PTR)NET_BUFFER_LIST_INFO(
 NetBufferList,TcpIpChecksumNetBufferListInfo);
```

If ChecksumInfo.Transmit.NdisPacketTcpChecksum is **TRUE**, the TCP send operation will be offloaded. If ChecksumInfo.Transmit.NdisPacketUdpChecksum is **TRUE**, the UDP send operation will be offloaded.

In Windows Vista with Service Pack 1 (SP1) and Windows Server 2008, if inMetaValues->headerIncludeHeaderLength is greater than 0, the outgoing packet is a RAW send reinjection that includes an IP header. To perform RAW send reinjections that include an IP header for Windows Vista with SP1 and Windows Server 2008, you must retreat the cloned packet by the amount in inMetaValues->headerIncludeHeaderLength and copy the inMetaValues->headerIncludeHeader over the newly extended space. Then, use FwpsInjectTransportSendAsync0 with the net buffer list for the packet and leave the FWPS_TRANSPORT_SEND_PARAMS0 parameter set to **NULL**. For more information about retreat operations for net buffer lists, see Retreat and Advance Operations.

Note For raw send operations, the net buffer list must contain only a single net buffer. If your net buffer list contains more than one net buffer, you have to convert your net buffer list to a series of net buffer lists, and each in the series must contain a single net buffer. For more information about net buffer list management, see NET_BUFFER Architecture.

Packet Modification Examples

Article • 05/09/2022

The following example code shows how to modify and inspect packets with WFP.

Inline packet Modification from Outgoing Transport Layers

```C++
HANDLE gInjectionHandle;

void
NTAPI
InjectionCompletionFn(
   IN void* context,
   IN OUT NET_BUFFER_LIST* netBufferList,
   IN BOOLEAN dispatchLevel
   )
{
   FWPS_TRANSPORT_SEND_PARAMS0* tlSendArgs
     = (FWPS_TRANSPORT_SEND_PARAMS0*)context;

   //
   // TODO: Free tlSendArgs and embedded allocations.
   //

   //
   // TODO: Check netBufferList->Status for injection result
   //

 FwpsFreeCloneNetBufferList0(netBufferList, 0);
}

void
NTAPI
WfpTransportSendClassify(
   IN const FWPS_INCOMING_VALUES0* inFixedValues,
   IN const FWPS_INCOMING_METADATA_VALUES0* inMetaValues,
   IN OUT void* layerData,
   IN const FWPS_FILTER0* filter,
   IN UINT64 flowContext,
   IN OUT FWPS_CLASSIFY_OUT0* classifyOut
   )
{
   NTSTATUS status;

   NET_BUFFER_LIST* netBufferList = (NET_BUFFER_LIST*)layerData;
   NET_BUFFER_LIST* clonedNetBufferList = NULL;
   FWPS_PACKET_INJECTION_STATE injectionState;
```

```
  FWPS_TRANSPORT_SEND_PARAMS0* tlSendArgs = NULL;
  ADDRESS_FAMILY af = AF_UNSPEC;

injectionState = FwpsQueryPacketInjectionState0(
gInjectionHandle,
netBufferList,
                       NULL);
if (injectionState == FWPS_PACKET_INJECTED_BY_SELF ||
injectionState == FWPS_PACKET_PREVIOUSLY_INJECTED_BY_SELF)
  {
classifyOut->actionType = FWP_ACTION_PERMIT;
goto Exit;
  }

if (!(classifyOut->rights & FWPS_RIGHT_ACTION_WRITE))
  {
     //
     // Cannot alter the action.
     //
goto Exit;
  }

  //
  // TODO: Allocate and populate tlSendArgs by using information from
  // inFixedValues and inMetaValues.
  // Note: 1) Remote address and controlData (if not NULL) must
  // be deep-copied.
  //       2) IPv4 address must be converted to network order.
  //       3) Handle allocation errors.

ASSERT(tlSendArgs != NULL);

status = FwpsAllocateCloneNetBufferList0(
netBufferList,
              NULL,
              NULL,
              0,
              &clonedNetBufferList);

if (!NT_SUCCESS(status))
  {
classifyOut->actionType = FWP_ACTION_BLOCK;
classifyOut->rights &= ~FWPS_RIGHT_ACTION_WRITE;

goto Exit;
  }

  //
  // TODO: Perform modification to the cloned net buffer list here.
  //

  //
  // TODO: Set af based on inFixedValues->layerId.
  //
ASSERT(af == AF_INET || af == AF_INET6);
```

```
   //
   // Note: For TCP traffic, FwpsInjectTransportReceiveAsync0 and
   // FwpsInjectTransportSendAsync0 must be queued and run by a DPC.
   //

 status = FwpsInjectTransportSendAsync0(
 gInjectionHandle,
               NULL,

Types of Callouts

Stream Inspection

Article • 10/26/2022

Inline Stream Inspection

Inline stream modifiers can edit stream data by permitting or blocking a part of the indicated data by setting the value of the **countBytesEnforced** member of the FWPS_STREAM_CALLOUT_IO_PACKET0 structure as they return **FWP_ACTION_PERMIT** or **FWP_ACTION_BLOCK** from the *classifyFn* callout function. They can also call the FwpsStreamInjectAsync0 function to add new content to the stream. This content can be new or can replace blocked data.

To replace a pattern found in the middle of an indicated segment (for example, *n* bytes followed by a pattern of *p* bytes followed by *m* bytes), the callout would follow these steps:

1. The callout's *classifyFn* function is called by using *n* + *p* + *m* bytes.

2. The callout returns **FWP_ACTION_PERMIT** with the **countBytesEnforced** member set to *n*.

3. The callout's *classifyFn* function is called again with *p* + *m* bytes. WFP will call *classifyFn* again if **countBytesEnforced** is less than the indicated amount.

4. From the *classifyFn* function, the callout calls the *FwpsStreamInjectAsync0* function to inject the replacement pattern *p*'. The callout then returns **FWP_ACTION_BLOCK** with **countBytesEnforced** set to *p*.

5. The callout's *classifyFn* function is called again with *m* bytes.

6. The callout returns **FWP_ACTION_PERMIT** with **countBytesEnforced** set to *m*.

If the indicated data is insufficient for the callout to make an inspection decision, it can set the **streamAction** member of the FWPS_STREAM_CALLOUT_IO_PACKET0 structure to **FWPS_STREAM_ACTION_NEED_MORE_DATA** and set the **countBytesRequired** member to the minimal amount WFP should accumulate before the data is indicated again. When **streamAction** is set, the callout should return **FWP_ACTION_NONE** from the *classifyFn* function.

WFP can accumulate up to 8 MB of stream data when **FWPS_STREAM_ACTION_NEED_MORE_DATA** is set. WFP will set the **FWPS_CLASSIFY_OUT_FLAG_BUFFER_LIMIT_REACHED** flag when it calls the callout's *classifyFn* function and the buffer space is exhausted. When the latter flag is set, the callout must accept the indicated data in full. A callout must not return **FWPS_STREAM_ACTION_NEED_MORE_DATA** when the **FWPS_CLASSIFY_OUT_FLAG_NO_MORE_DATA** flag is set.

For the convenience of being able to scan a stream pattern from a flat buffer, WFP provides the FwpsCopyStreamDataToBuffer0 utility function, which can copy indicated stream data into a contiguous buffer.

Out-of-Band Stream Inspection

For out-of-band inspection or modification, a stream callout would follow the similar pattern as the packet inspection callout: it would first clone all indicated stream segments for deferred processing, and then it would block those segments. The inspected or modified data is later injected back into the data stream. When injecting data out-of-band, the callout must return **FWP_ACTION_BLOCK** on all indicated segments to guarantee integrity of the resulting stream. An out-of-band inspection module must not arbitrarily inject a FIN (which indicates no more data from the sender) into an outgoing data stream. If the module must drop the connection, its *classifyFn* callout function must set the **streamAction** member of the FWPS_STREAM_CALLOUT_IO_PACKET0 structure to **FWPS_STREAM_ACTION_DROP_CONNECTION**.

Note It is a **violation of contract** for callouts to switch from out-of-band to inline, and can cause unexpected behaviors. Ensure out-of-band callouts are meeting each of the specified criteria.

Because stream data can be indicated as a NET_BUFFER_LIST chain, FWP provides the FwpsCloneStreamData0 and FwpsDiscardClonedStreamData0 utility functions that operate on net buffer list chains.

WFP also supports stream data throttling for the incoming direction. If a callout cannot keep pace with the incoming data rate, it can return **FWPS_STREAM_ACTION_DEFER** to "pause" the stream. The stream can then be "resumed" by calling the FwpsStreamContinue0 function. Deferring a stream with this function causes the TCP/IP stack to stop ACK-processing incoming data. This causes the TCP sliding window to decrease toward 0.

For out-of-band stream inspection callouts, FwpsStreamContinue0 must not be called while the **FwpsStreamInjectAsync0** function is called.

Injected stream data will not be re-indicated to the callout, but it will be made available to stream callouts from lower-weight sublayers.

The Windows Filtering Platform Stream Edit Sample in the Windows driver samples repository on GitHub shows how to perform inline and out-of-band editing at the stream layer.

Note Windows Server 2008 and later do not support removal of a stream filter during the following processes:

- The callout is performing out-of-band packet injection.
- The callout is requesting more data by setting the **streamAction** member of the FWPS_STREAM_CALLOUT_IO_PACKET0 structure to **FWPS_STREAM_ACTION_NEED_MORE_DATA**.
- The callout is deferring a stream by setting the **streamAction** member of the FWPS_STREAM_CALLOUT_IO_PACKET0 structure to **FWPS_STREAM_ACTION_DEFER**.

Dynamic Stream Inspection

Windows 7 and later support dynamic stream inspections. A dynamic stream inspection operates on an existing stream data flow, rather than creating and tearing down a new one. A callout driver that can perform dynamic stream inspections should set the **FWP_CALLOUT_FLAG_ALLOW_MID_STREAM_INSPECTION** flag in the **Flags** member of the FWPS_CALLOUT1 or FWPS_CALLOUT2 structure.

Avoiding Unnecessary Inspections

To perform stream inspections only on connections that the driver is interested in, a callout can set the **FWP_CALLOUT_FLAG_CONDITIONAL_ON_FLOW** flag in the **Flags** member of the FWPS_CALLOUT0 structure. This callout will be ignored on all other connections. Performance will be improved and the driver will not have to maintain unnecessary state data.

Stream Layer Waterfall Model

The stream layer in WFP follows a strict waterfall model; that is, a callout in this layer will be allowed to inspect a stream segment only if the previous callout (if any) explicitly permitted it. If a callout blocks an indicated segment, that segment is permanently taken out of the stream and no callouts will be allowed to inspect it.

Moreover:

1. Every non-inspect callout at the stream layer must explicitly assign a value to the **actionType** member of the *classifyOut* parameter regardless of what value may have been previously set in that parameter.
2. The **FWPS_RIGHT_ACTION_WRITE** flag in the **rights** member of the *classifyOut* parameter has no significance in the WFP stream layer. Callouts at this layer should not check for the presence of this flag. Callouts may process the indicated *layerData* parameter regardless of the value of *classifyOut*->**rights**.

Modifying Stream Data

Article • 12/15/2021

When a callout processes data at the stream layer, its *classifyFn* callout function can modify the data in the data stream. The callout's *classifyFn* callout function permits acceptable data in the stream to pass through unaltered, blocks data in the stream that is to be removed, and injects new or altered data into the stream when it is suitable.

A callout can replace data in the stream with other data by blocking the data that is to be replaced, and, at the same time, injecting the new data into the stream. In this situation, the new data is injected into the stream at the same point where the blocked data is removed from the stream.

For a callout driver to inject data into a data stream, it must first create an injection handle. This can be the same injection handle that is created for injecting modified packet data back into the network stack. See Inspecting Packet and Stream Data for information about how to create an injection handle.

For information about how to modify stream data, see the "Windows Filtering Platform Stream Edit Sample" in the Hardware Samples code gallery.

Data Logging

Article • 12/15/2021

To determine what data should be logged, a callout's classifyFn callout function can inspect any combination of the data fields, the metadata fields, and any raw data that is passed to it, as well as any relevant data that has been stored in a context associated with the filter or the data flow.

For example, if a callout keeps track of how many incoming (inbound) IPv4 packets are discarded by a filter at the network layer, the callout is added to the filter engine at the FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD layer. In this situation, the callout's classifyFn callout function might resemble the following example:

```C++
ULONG TotalDiscardCount = 0;
ULONG FilterDiscardCount = 0;

// classifyFn callout function
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    IN OUT FWPS_CLASSIFY_OUT  *classifyOut
    )
{
  // Increment the total count of discarded packets
 InterlockedIncrement(&TotalDiscardCount);

  // Check whether a discard reason metadata field is present
 if (FWPS_IS_METADATA_FIELD_PRESENT(
 inMetaValues,
        FWPS_METADATA_FIELD_DISCARD_REASON))
  {
    // Check whether it is a general discard reason
 if (inMetaValues->discardMetadata.discardModule ==
        FWPS_DISCARD_MODULE_GENERAL)
    {
      // Check whether discarded by a filter
 if (inMetaValues->discardMetadata.discardReason ==
          FWPS_DISCARD_FIREWALL_POLICY)
      {
        // Increment the count of packets discarded by a filter
 InterlockedIncrement(&FilterDiscardCount);
      }
    }
  }

  // Take no action on the data
 classifyOut->actionType = FWP_ACTION_CONTINUE;
}
```

Associating Context with a Data Flow

Article • 12/15/2021

For callouts that process data at a filtering layer that supports data flows, the callout driver can associate a context with each data flow. Such a context is opaque to the filter engine. The callout's classifyFn callout function can use this context to save state information specific to the data flow for the next time that it is called by the filter engine for that data flow. The filter engine passes this context to the callout's classifyFn callout function through the *flowContext* parameter. If no context is associated with the data flow, the *flowContext* parameter is zero.

To associate a context with a data flow, a callout's classifyFn callout function calls the **FwpsFlowAssociateContext0** function. For example:

C++

```
// Context structure to be associated with data flows
typedef struct FLOW_CONTEXT_ {
  .
  .  // Driver-specific content
  .
} FLOW_CONTEXT, *PFLOW_CONTEXT;

#define FLOW_CONTEXT_POOL_TAG 'fcpt'

// classifyFn callout function
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    IN OUT FWPS_CLASSIFY_OUT  *classifyOut
  )
{
  PFLOW_CONTEXT context;
  UINT64 flowHandle;
  NTSTATUS status;

  ...

  // Check for the flow handle in the metadata
  if (FWPS_IS_METADATA_FIELD_PRESENT(
      inMetaValues,
      FWPS_METADATA_FIELD_FLOW_HANDLE))
  {
    // Get the flow handle
    flowHandle = inMetaValues->flowHandle;
    // Allocate the flow context structure
    context =
      (PFLOW_CONTEXT)ExAllocatePoolWithTag(
        NonPagedPool,
        sizeof(FLOW_CONTEXT),
        FLOW_CONTEXT_POOL_TAG
      );

    // Check the result of the memory allocation
    if (context == NULL)
    {

      // Handle memory allocation error
      ...
    }
    else
    {

      // Initialize the flow context structure
      ...

      // Associate the flow context structure with the data flow
      status = FwpsFlowAssociateContext0(
                 flowHandle,
                 FWPS_LAYER_STREAM_V4,
                 calloutId,
                 (UINT64)context
               );

      // Check the result
      if (status != STATUS_SUCCESS)
      {
        // Handle error
        ...
      }
    }
  }

  ...

}
```

If a context is already associated with a data flow, it must first be removed before a new context may be associated with the data flow. To remove a context from a data flow, a callout's classifyFn callout function calls the **FwpsFlowRemoveContext0** function. For example:

C++

```
// Context structure to be associated with data flows
typedef struct FLOW_CONTEXT_ {
  ...
} FLOW_CONTEXT, *PFLOW_CONTEXT;

#define FLOW_CONTEXT_POOL_TAG 'fcpt'

// classifyFn callout function
VOID NTAPI
 ClassifyFn(
    IN const FWPS_INCOMING_VALUES0  *inFixedValues,
    IN const FWPS_INCOMING_METADATA_VALUES0  *inMetaValues,
    IN OUT VOID  *layerData,
    IN const FWPS_FILTER0  *filter,
    IN UINT64  flowContext,
    OUT FWPS_CLASSIFY_OUT  *classifyOut
  )
{
  PFLOW_CONTEXT context;
  UINT64 flowHandle;
  NTSTATUS status;

  ...

  // Check for the flow handle in the metadata
 if (FWPS_IS_METADATA_FIELD_PRESENT(
    inMetaValues,
    FWPS_METADATA_FIELD_FLOW_HANDLE))
  {
    // Get the flow handle
     flowHandle = inMetaValues->flowHandle;

    // Check whether there is a context associated with the data flow
     if (flowHandle != 0)
     {
        // Get a pointer to the flow context structure
        context = (PFLOW_CONTEXT)flowContext;

        // Remove the flow context structure from the data flow
        status = FwpsFlowRemoveContext0(
                  flowHandle,
                  FWPS_LAYER_STREAM_V4,
                  calloutId
                );

      // Check the result
      if (status != STATUS_SUCCESS)
      {
        // Handle error
        ...
      }

      // Cleanup the flow context structure
      ...

      // Free the memory for the flow context structure
      ExFreePoolWithTag(
        context,
        FLOW_CONTEXT_POOL_TAG
        );
    }
  }

  ...

}
```

In the previous examples, the *calloutId* variable contains the run-time identifier for the callout. The run-time identifier is the same identifier that was returned to the callout driver when the callout driver registered the callout with the filter engine.

Processing Classify Callouts Asynchronously

Article • 12/15/2021

A WFP callout driver can authorize or deny a network operation, or admit or discard a network packet, by returning the action types **FWP_ACTION_PERMIT**, **FWP_ACTION_CONTINUE**, or **FWP_ACTION_BLOCK** from the *classifyFn* callout function. Frequently a callout driver cannot return an inspection decision from its *classifyFn* function until the indicated information, such as classifiable fields, metadata, or packets, can be forwarded for processing to another component, such as a user-mode application. In these cases a decision may have to be made asynchronously at some later time.

General Rules for Asynchronous Processing

WFP supports asynchronous processing of the *classifyFn* callout function. However, the mechanism for doing this differs according to the different layers.

Asynchronous ALE Classify
A callout driver must call the **FwpsPendOperation0** function from *classifyFn*. The asynchronous operation must be completed with a call to the **FwpsCompleteOperation0** function.

Asynchronous Packet Classify
A callout driver should return **FWP_ACTION_BLOCK** from the *classifyFn* function, with the **FWPS_CLASSIFY_OUT_FLAG_ABSORB** flag set. Network packets must be referenced or cloned. The asynchronous operation is completed by either reinjecting the cloned or modified packet or by silently discarding the packet.

Asynchronous ALE Classify That Includes Packets
A combination of the previous two procedures is used: the classify operation is pended and the packet is referenced or cloned, and at some time later the call to *classifyFn* is completed and the cloned packet is reinjected or discarded.

Special Cases and Considerations

ALE Connect vs. Receive/Accept Layers
When **FwpsCompleteOperation0** is called to complete a pended classify operation at an ALE connect layer (**FWPS_LAYER_ALE_AUTH_CONNECT_V4** or **FWPS_LAYER_ALE_AUTH_CONNECT_V6**), an ALE reauthorization classify operation is

triggered at the respective ALE connect layer. The callout driver should return an inspection decision from this reauthorization classify operation. You can detect an ALE reauthorization classify operation by checking whether the **FWP_CONDITION_FLAG_IS_REAUTHORIZE** flag is set.

The callout driver must maintain a unique state for each pended ALE_AUTH_CONNECT classify operation in such a way that the inspection decision for each classify operation can be looked up during a **FwpsCompleteOperation0**-triggered reauthorization. If packets are referenced or cloned during a pended ALE_AUTH_CONNECT classify operation (for example, for non-TCP connections), they can be reinjected after reauthorization occurs.

When **FwpsCompleteOperation0** is called during with a classify operation at an ALE receive/accept layer (**FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4** or **FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6**), **FwpsCompleteOperation0** does not trigger an ALE reauthorization. Instead a new call to *classifyFn* is made again when the cloned packet is reinjected incoming if the modification was not significant enough to bypass the filter. Permitting the self-injected clone from the ALE_RECV_ACCEPT layer effectively authorizes the incoming connection. If the incoming connection is not to be allowed, discard the incoming packet after it calls **FwpsCompleteOperation0**.

ALE Reauthorization
A callout driver can be reclassified at an ALE connect or receive/accept layer for events such as a policy change (for example, adding or removing a filter at the layer), detecting a new arrival interface, and re-keying a connection by using IPsec. Such a reauthorization cannot be pended by calling **FwpsCompleteOperation0**, and it is not necessary to do so. A callout driver should use the rules listed previously to process packets that are indicated during reauthorization.

Be aware that both incoming and outgoing packet can be reauthorized at ALE_AUTH_CONNECT or ALE_RECV_ACCEPT layers. For example, an incoming packet can be reauthorized at the ALE_AUTH_CONNECT layer. A callout driver must not assume that the direction of the packet is the same as the direction of the connection.

ALE_FLOW_ESTABLISHED Layers
Asynchronous processing is not supported at these layers (**FWPS_LAYER_ALE_FLOW_ESTABLISHED_V4** or **FWPS_LAYER_ALE_FLOW_ESTABLISHED_V6**).

INBOUND_TRANSPORT Layers
A callout driver must not perform asynchronous processing of packets that require ALE classify processing at an incoming (inbound) transport layer (**FWPS_LAYER_INBOUND_TRANSPORT_V4** or

FWPS_LAYER_INBOUND_TRANSPORT_V6). Doing this can interfere with flow creation. When WFP calls the *classifyFn* callout function at an incoming transport layer, it sets the **FWPS_METADATA_FIELD_ALE_CLASSIFY_REQUIRED** flag for those packets that require ALE classify processing. A callout driver should permit such packets from an INBOUND_TRANSPORT layer and should defer processing them until they reach an ALE_RECV_ACCEPT layer.

STREAM Layers

At a stream layer (**FWPS_LAYER_STREAM_V4** or **FWPS_LAYER_STREAM_V6**), TCP data segments are indicated instead of an IP or TCP header. The stream layer is also where a chain of net buffer lists can be indicated in one call to the *classifyFn* callout function. WFP makes available specialized clone and injection functions, **FwpsCloneStreamData0** and **FwpsStreamInjectAsync0**, for stream layer callouts to use.

Because of the ordered delivery nature of stream layer data, a callout driver must continue to clone and absorb data as long any stream data is still pending. Mixing asynchronous and synchronous operations for a given stream flow can result in undefined behavior.

Using Bind or Connect Redirection

Article • 09/27/2024

The connect/bind redirection feature of the Windows Filtering Platform (WFP) enables application layer enforcement (ALE) callout drivers to inspect and, if desired, redirect connections.

This feature is available in Windows 7 and later.

Note The ClassifyFunctions_ProxyCallouts.cpp module in the WFP driver sample includes code that demonstrates connect/bind redirection.

A WFP connection redirection callout redirects an application's connection request so that the application connects to a proxy service instead of the original destination. The proxy service has two sockets: one for the redirected original connection and one for the new proxied outbound connection.

A WFP redirect record is a buffer of opaque data that WFP must set on an outbound proxy connection at the **FWPM_LAYER_ALE_AUTH_CONNECT_REDIRECT_V4** and **FWPM_LAYER_ALE_AUTH_CONNECT_REDIRECT_V6** layers, so that the redirected connection and the original connection are logically related.

Changing the local address and port of a flow is only supported in the bind-redirect layer. This functionality isn't supported in the connect-redirect layer.

Layers Used for Redirection

Callout drivers can preform redirection at the following layers, which are called "redirect layers":

- FWPM_LAYER_ALE_BIND_REDIRECT_V4 (FWPS_LAYER_ALE_BIND_REDIRECT_V4)
- FWPM_LAYER_ALE_BIND_REDIRECT_V6 (FWPS_LAYER_ALE_BIND_REDIRECT_V6)
- FWPM_LAYER_ALE_CONNECT_REDIRECT_V4 (FWPS_LAYER_ALE_CONNECT_REDIRECT_V4)
- FWPM_LAYER_ALE_CONNECT_REDIRECT_V6 (FWPS_LAYER_ALE_CONNECT_REDIRECT_V6)

The layer at which redirection is performed determines the effect of the change. Changes at connect layers affect only the flow being connected. Changes at bind layers affect all connections that are using that socket.

The redirect layers are only available for Windows 7 and later versions of Windows. Callout drivers that support classification at these layers must register using **FwpsCalloutRegister1** or higher, not the older **FwpsCalloutRegister0** function.

ⓘ **Important**

Redirection is not available for use with all types of network traffic. The types of packets that are supported for redirection are shown in the following list:

- TCP
- UDP
- Raw UDPv4 without the header include option
- Raw ICMP

Performing Redirection

To redirect a connection, the callout driver must obtain a writable copy of the TCP 4-tuple information, make changes to it as needed, and apply the changes. A set of new functions are provided to obtain writable layer data and to apply it through the engine. Callout drivers have the option of making changes either inline in their classifyFn functions, or asynchronously in another function.

Callout drivers that implement redirection must use *classifyFn1* or later instead of *classifyFn0* as their classification callout function. To use *classifyFn1* or later, the callout must be registered by calling **FwpsCalloutRegister1** or later, not the older **FwpsCalloutRegister0**.

To perform redirection inline a callout driver must perform the following steps in its implementation of classifyFn:

1. Call **FwpsRedirectHandleCreate0** to obtain a handle that can be used to redirect TCP connections. This handle should be cached and used for all redirections. (This step is omitted for Windows 7 and earlier.)

2. In Windows 8 and later, you must query the redirection state of the connection by using the **FwpsQueryConnectionRedirectState0** function in your callout driver. This must be done to prevent infinite redirecting.

3. Call **FwpsAcquireClassifyHandle0** to obtain a handle that will be used for subsequent function calls.

4. Call **FwpsAcquireWritableLayerDataPointer0** to get the writable data structure for the layer in which classifyFn was called. Cast the *writableLayerData* out parameter to the structure corresponding to the layer, either **FWPS_BIND_REQUEST0** or **FWPS_CONNECT_REQUEST0**.

   Starting with Windows 8, if your callout driver is redirecting to a local service, you must call **FwpsRedirectHandleCreate0** to fill in the **localRedirectHandle** member of the **FWPS_CONNECT_REQUEST0** structure in order to make local proxying work.

5. Make changes to the layer data as needed:

   a. Save the original destination in the local redirect context as shown in the following example:

   C++

   ```
   FWPS_CONNECT_REQUEST* connectRequest = redirectContext-
   >connectRequest;
   // Replace "..." with your own redirect context size
   connectRequest->localRedirectContextSize = ...;
   // Store original destination IP/Port information in the
   localRedirectContext member
   connectRequest->localRedirectContext =    ExAllocatePoolWithTag(…);
   ```

   b. Modify the remote address as shown in the following example:

   C++

   ```
   // Ensure we don't need to worry about crossing any of the TCP/IP
   stack's zones
   if(INETADDR_ISANY((PSOCKADDR)&(connectRequest-
   >localAddressAndPort)))
   {
      INETADDR_SETLOOPBACK((PSOCKADDR)&(connectRequest-
   >remoteAddressAndPort));
   }
   else
   {
      INETADDR_SET_ADDRESS((PSOCKADDR)&(connectRequest-
   >remoteAddressAndPort),
                             INETADDR_ADDRESS((PSOCKADDR)&
   (connectRequest->localAddressAndPort)));
   }
   INETADDR_SET_PORT((PSOCKADDR)&connectRequest->remoteAddressAndPort,
                     RtlUshortByteSwap(params->proxyPort));
   ```

   c. If your callout driver is redirecting to a local service, it should set the local proxy PID in the **localRedirectTargetPID** member of the **FWPS_CONNECT_REQUEST0** structure.

d. If your callout driver is redirecting to a local service, it should set the redirect handle returned by FwpsRedirectHandleCreate0 in the **localRedirectHandle** member of the FWPS_CONNECT_REQUEST0 structure.

6. Call FwpsApplyModifiedLayerData0 to apply the changes made to the data.

7. In your proxy service (which could be in user mode or kernel mode), you must query redirect records and contexts as shown in the following example:

   C++

   ```cpp
   BYTE* redirectRecords;
   BYTE redirectContext[CONTEXT_SIZE];
   listenSock = WSASocket(…);
   result = bind(listenSock, …);
   result = listen(listenSock, …);
   clientSock = WSAAccept(listenSock, …);
   // opaque data to be set on proxy connection
   result = WSAIoctl(clientSock,
                     SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS,
                     redirectRecords, …);
   // callout allocated data, contains original destination information
   result = WSAIoctl(clientSock,
                     SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT,
                     redirectContext, …);
   // extract original destination IP and port from above context
   ```

8. In your proxy service (which could be in user mode or kernel mode), you must set redirect records on the proxy connection socket as shown in the following example to create a new outbound socket:

   C++

   ```cpp
   proxySock = WSASocket(…);
   result = WSAIoctl(
                 proxySock,
                 SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS,
                 redirectRecords, …);
   ```

9. Call FwpsReleaseClassifyHandle0 to release the classification handle obtained in step 2.

10. Call FwpsRedirectHandleDestroy0 to destroy the handle that was obtained in step 1.

To perform redirection asynchronously a callout driver must perform the following steps:

1. Call **FwpsRedirectHandleCreate0** to obtain a handle that can be used to redirect TCP connections. (This step is omitted for Windows 7 and earlier.)

2. In Windows 8 and later, you must query the redirection state of the connection by using the **FwpsQueryConnectionRedirectState0** function in your callout driver.

3. Call **FwpsAcquireClassifyHandle0** to obtain a handle that will be used for subsequent function calls. This step and steps 2 and 3 are performed in the callout driver's classifyFn callout function.

4. Call **FwpsPendClassify0** to put the classification in a pending state as shown in the following example:

   C++

   ```
   FwpsPendClassify(
           redirectContext->classifyHandle,
           0,
           &redirectContext->classifyOut);
   classifyOut->actionType = FWP_ACTION_BLOCK;
   classifyOut->rights &= ~FWPS_RIGHT_ACTION_WRITE;
   ```

> ⓘ **Note**
>
> If you are targeting Windows 7, you must perform the following steps in a separate worker function. If you are targeting Windows 8 or later, you can perform all steps for asynchronous redirection from within the *classifyFn* and ignore Step 5.

5. Send the classification handle and the writable layer data to another function for asynchronous processing. The remaining steps are performed in that function, not in the callout driver's implementation of classifyFn.

6. Call **FwpsAcquireWritableLayerDataPointer0** to get the writable data structure for the layer in which classifyFn was called. Cast the *writableLayerData* out parameter to the structure corresponding to the layer, either **FWPS_BIND_REQUEST0** or **FWPS_CONNECT_REQUEST0**.

   Starting with Windows 8, if your callout driver is redirecting locally, you must call **FwpsRedirectHandleCreate0** to fill in the **localRedirectHandle** member of the **FWPS_CONNECT_REQUEST0** structure in order to make proxying work.

7. Store any callout-specific context information in a private context structure as shown in the following example:

C++

```
redirectContext->classifyHandle = classifyHandle;
redirectContext->connectRequest = connectRequest;
redirectContext->classifyOut = *classifyOut; // deep copy
// store original destination IP, port
```

8. Make changes to the layer data as needed.

9. Call FwpsApplyModifiedLayerData0 to apply the changes made to the data. Set the **FWPS_CLASSIFY_FLAG_REAUTHORIZE_IF_MODIFIED_BY_OTHERS** flag if you wish to be re-authorized in the event that another callout modifies the data further.

10. Call FwpsCompleteClassify0 to complete the classify operation asynchronously as shown in the following example:

C++

```
FwpsCompleteClassify(
        redirectContext->classifyHandle,
        0,
        &redirectContext->classifyOut);
classifyOut->actionType = FWP_ACTION_PERMIT;
classifyOut->rights |= FWPS_RIGHT_ACTION_WRITE;
```

11. Call FwpsReleaseClassifyHandle0 to release the classification handle obtained in step 1.

Handling Connect Redirection from Multiple Callouts

It's possible that more than one callout driver will initiate connect redirection for the same flow. Callouts that perform connect redirection should be aware of other requests and respond appropriately.

The **FWPS_RIGHT_ACTION_WRITE** flag should be set whenever a callout pends a classification. Your callout should test for the **FWPS_RIGHT_ACTION_WRITE** flag to check the rights for your callout to return an action. If this flag isn't set, your callout can still return a **FWP_ACTION_BLOCK** action in order to veto a **FWP_ACTION_PERMIT** action that was returned by a previous callout.

In Windows 8 and later, your callout driver must query the redirection state of the connection (to see if your callout driver or another callout driver has modified it) by using the FwpsQueryConnectionRedirectState0 function. If the connection is redirected by your callout driver, or if it was previously redirected by your callout driver, the callout driver should do nothing. Otherwise, it should also check for local redirection as shown in the following example:

C++

```cpp
FwpsAcquireWritableLayerDataPointer(...,(PVOID*)&connectRequest), ...);
if(connectRequest->previousVersion->modifierFilterId != filterId)
{
    if(connectRequest->previousVersion->localRedirectHandle)
    {
        classifyOut->actionType = FWP_ACTION_PERMIT;
        classifyOut->rights &= FWPS_RIGHT_ACTION_WRITE;
        FwpsApplyModifiedLayerData(
                classifyHandle,
                (PVOID)connectRequest,
                FWPS_CLASSIFY_FLAG_REAUTHORIZE_IF_MODIFIED_BY_OTHERS);
    }
}
```

If the connection is to a local proxy, your callout driver shouldn't attempt to redirect it.

Callout drivers that use connect redirection should register at the ALE authorization connect layer (**FWPS_LAYER_ALE_AUTH_CONNECT_V4** or **FWPS_LAYER_ALE_AUTH_CONNECT_V6**) and check the following two metadata values for indications where the **FWP_CONDITION_FLAG_IS_CONNECTION_REDIRECTED** flag is set:

- **FWPS_METADATA_FIELD_LOCAL_REDIRECT_TARGET_PID** contains the process identifier for the process that is responsible for the redirected flow.
- **FWPS_METADATA_FIELD_ORIGINAL_DESTINATION** contains the address of the original destination for the flow.

The FWPS_CONNECT_REQUEST0 structure contains a member called **localRedirectTargetPID**. For any loopback connect redirection to be valid, this field must be populated with the PID of the process that will be responsible for the redirected flow. This is the same data that the engine passes at the ALE authorization connect layers as **FWPS_METADATA_FIELD_LOCAL_REDIRECT_TARGET_ID**.

Starting with Windows 8, the proxy service needs to issue the SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS and SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT IOCTLs, using WSAIoctl, against the original endpoint of the proxy service. Additionally, the SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS IOCTL must be issued, using **WSAIoctl**, on the new (proxied) socket.

ALE Endpoint Lifetime Management

Article • 12/15/2021

A callout driver that supports application layer enforcement (ALE) may need to allocate resources to process indications. This topic describes how to configure a callout driver to release such resources when the associated endpoint is closed. ALE endpoint lifetime management is supported in Windows 7 and later versions of Windows.

To manage resources associated with ALE endpoints, a callout driver can register at the following layers:

- FWPS_LAYER_ALE_RESOURCE_RELEASE_V4 (FWPM_LAYER_ALE_RESOURCE_RELEASE_V4)
- FWPS_LAYER_ALE_RESOURCE_RELEASE_V6 (FWPM_LAYER_ALE_RESOURCE_RELEASE_V6)
- FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V4 (FWPM_LAYER_ALE_ENDPOINT_CLOSURE_V4)
- FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V6 (FWPM_LAYER_ALE_ENDPOINT_CLOSURE_V6)

An ALE resource release layer is indicated for every indication at the corresponding ALE resource assignment layer (for example, FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V4). To ensure that callout drivers can match the release layer to the assignment layer, the FWPS_METADATA_FIELD_TRANSPORT_ENDPOINT_HANDLE metadata field is provided at both layers and each endpoint is assigned a unique handle.

ALE endpoint closure layers are invoked differently depending on the type of endpoint. For TCP connections, an ALE endpoint closure is indicated for every ALE authorize connect layer (for example FWPS_LAYER_ALE_AUTH_CONNECT_V4) or ALE authorize receive accept layer (for example FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4) indication. As with ALE resource release indications, the engine assigns a unique handle for each endpoint and passes it in the FWPS_METADATA_FIELD_TRANSPORT_ENDPOINT_HANDLE metadata field. For non-TCP endpoints, an ALE endpoint closure layer is invoked for each endpoint regardless of the number of unique remote peers the socket communicates with. An ALE endpoint closure layer is also invoked for each TCP listening socket.

Callouts registered for an ALE endpoint closure layer can pend classification. This enables the callout to reinject any packets queued for asynchronous processing before the endpoint is shut down. To pend classification, the callout driver must call **FwpsPendClassify0** followed by a call to **FwpsCompleteClassify0** when processing is complete.

When applicable, the engine will indicate a unique handle for the parent endpoint in the FWPS_METADATA_FIELD_PARENT_ENDPOINT_HANDLE metadata field. This enables the callout driver to track parent/child relationships, if required.

Processing Flow Delete Callouts

Article • 12/15/2021

When a data flow that is being processed by a callout is stopped, the filter engine calls the callout's *flowDeleteFn* callout function if the callout driver previously associated a context with the data flow. A callout's *flowDeleteFn* callout function performs any necessary clean up of the context that the callout driver associated with the data flow before the data flow is stopped.

For example:

```C++
// Context structure to be associated with data flows
typedef struct FLOW_CONTEXT_ {
  ...
} FLOW_CONTEXT, *PFLOW_CONTEXT;

#define FLOW_CONTEXT_POOL_TAG 'fcpt'

// flowDeleteFn callout function
VOID NTAPI
 FlowDeleteFn(
    IN UINT16  layerId,
    IN UINT32  calloutId,
    IN UINT64  flowContext
    )
{
  PFLOW_CONTEXT context;

  // Get the flow context structure
 context = (PFLOW_CONTEXT)flowContext;

  // Cleanup the flow context structure
  ...

  // Free the memory for the flow context structure
 ExFreePoolWithTag(
 context,
    FLOW_CONTEXT_POOL_TAG
    );
}
```

The filter engine automatically removes the context that a callout associated with a data flow when the data flow is stopped. Therefore, a callout is not required to call the **FwpsFlowRemoveContext0** function from its *flowDeleteFn* callout function to remove the context from the data flow.

Using Packet Tagging

Article • 12/15/2021

A callout driver can tag packets of interest and receive notification of events that happen to the tagged packets. Packet tagging is supported in Windows 7 and later versions of Windows.

To use packet tagging, the callout driver must implement the *FWPS_NET_BUFFER_LIST_NOTIFY_FN0* or *FWPS_NET_BUFFER_LIST_NOTIFY_FN1* callback function. This function will receive all of the status notifications for the tagged packets. Before individual packets can be tagged, the callout driver must obtain a special context tag by calling **FwpsNetBufferListGetTagForContext0**. The callout driver can use the same context tag for some or all of the tagged packets. For example, a callout driver might differentiate between types of tagged packets by using different context tags.

To tag packets, the callout driver uses **NET_BUFFER_LIST** structures. The callout driver makes calls to **FwpsNetBufferListAssociateContext0** to tag individual **NET_BUFFER_LIST** structures. The context the callout driver associates with the packet is an arbitrary unsigned 64-bit value. When an event is triggered, the *FWPS_NET_BUFFER_LIST_NOTIFY_FN0* or *FWPS_NET_BUFFER_LIST_NOTIFY_FN1* callback passes the context as an input parameter so that the callout driver can identify individual tagged packets. The context is not used or evaluated by the filtering engine. It is only passed to the callback for use by the callout driver.

Contexts are removed from tagged packets automatically when the packets leave the stack. However, if the packets never enter the TCP/IP stack — for example, in the case of an NDIS filter driver — the contexts will need to be removed manually by calling **FwpsNetBufferListRemoveContext0** with the *netBufferList* parameter set to **NULL**.

If a callout needs to abort tagging operations early, contexts can be removed by calling **FwpsNetBufferListRemoveContext0**. Removing a context generally triggers an **FWPS_NET_BUFFER_LIST_CONTEXT_REMOVED** event. For more information about the events that can be triggered, see the **FWPS_NET_BUFFER_LIST_EVENT_TYPE0** enumeration. In some cases no event will be triggered, such as when the packet never enters the TCP/IP stack for processing.

When a tagged packet is cloned, the callout driver can move or copy the context to the clone packet. To move the context (in the case of a clone), the callout driver must call **FwpsNetBufferListRetrieveContext0** with the *removeContext* parameter set to **TRUE**. Then the context can be associated with the new packet. The process for copying the context (in the case of a duplication) is the same except that the *removeContext* parameter of **FwpsNetBufferListRetrieveContext0** must be set to **FALSE**.

Packets tagged from TCP/IP layers can be retrieved from an NDIS filter driver. The reverse is also true. Packet tagging is not available from stream layers where no packets are indicated except data segments.

A callout driver can retrieve the context for a packet outside of the *FWPS_NET_BUFFER_LIST_NOTIFY_FN0* or *FWPS_NET_BUFFER_LIST_NOTIFY_FN1* function by calling **FwpsNetBufferListRetrieveContext0**. Typically, a callout driver will retrieve the context in its classifyFn callback.

Using Layer 2 Filtering

Article • 12/15/2021

Layer 2 filtering is supported in Windows 8 and later versions of Windows.

This WFP feature allows filtering on fields of the layer 2 MAC header. These layers are invoked on a per-packet basis for all packets that are sent or received by the host machine. The layers are invoked prior to packet reassembly on the inbound path and after packet fragmentation on the outbound path. These layers are accessed from an NDIS lightweight filter (LWF) driver.

> ⓘ **Note**
>
> A callout should not inject packets at a layer if it does not already have a corresponding filter at that layer. The injection of the **NET_BUFFER_LIST** structures should be coordinated with the filter addition and removal so that injection is only performed when the filter exists in the corresponding layer. In addition, providers should not remove filters that belong to other providers.

This section includes the following topics:

- Injecting MAC Frames
- Classifying Chained Network Buffer Lists
- WFP Layer 2 Layers and Fields

Injecting MAC Frames

A callback driver calls the **FwpsInjectMacReceiveAsync0** function to reinject a previously absorbed MAC frame (or a clone of the frame) back to the layer 2 inbound data path it was intercepted from, or to inject an invented MAC frame in the inbound data path.

A callback driver calls the **FwpsInjectMacSendAsync0** function to reinject a previously absorbed MAC frame (or a clone of the frame) back to the layer 2 outbound data path it was intercepted from, or to inject an invented MAC frame in the outbound data path.

The *netBufferLists* parameter can be a NET_BUFFER_LIST chain. However the completion function could be invoked multiple times each, completing a segment (or single NET_BUFFER_LIST) of the chain.

Injected frames could get classified again if the packets match the same filter as originally classified. Therefore, as with callouts at IP layers, layer 2 callouts must also protect against infinite packet inspection by calling **FwpsQueryPacketInjectionState0**.

Also, you must have callouts at the layer where you inject. Otherwise, your injected NET_BUFFER_LIST will not be completed to your completion function, and the NET_BUFFER_LIST will go further up the stack. In this case, the behavior is undefined, because NDIS will try to pass the injected NET_BUFFER_LIST to the next component in the stack.

The NET_BUFFER_LIST**Status** member contains the stack injection’s status result. The stack injection’s status result is the status that the stack puts in the NET_BUFFER_LIST after a WFP injection function returns **STATUS_SUCCESS**. You should use the **NT_SUCCESS** macro to check the stack injection's status in the **Status** member. If the **Status** value is **STATUS_SUCCESS**, the injection succeeded with no further information. **Status** member values that are greater than **STATUS_SUCCESS** mean that the injection succeeded, but there might be more information about the injection that should be considered. **Status** member values that are less than **STATUS_SUCCESS** mean that the injection failed for the reason specified in the **Status** member.

Classifying Chained Network Buffer Lists

By default, a callout driver can only classify network buffer lists individually. However, a callout driver can classify NET_BUFFER_LIST chains for better performance, if it does both of the following:

- Specifies the **FWP_CALLOUT_FLAG_ALLOW_L2_BATCH_CLASSIFY** flag in the **Flags** member of the **FWPS_CALLOUT2** structure.
- Registers a *classifyFn2* function that can classify NET_BUFFER_LIST chains.

⚠ Warning

However, if a callout driver does set the **FWP_CALLOUT_FLAG_ALLOW_L2_BATCH_CLASSIFY** flag, it cannot use the following functions to modify NET_BUFFER_LISTs.

- FwpsReferenceNetBufferList0
- FwpsDereferenceNetBufferList0
- FwpsAllocateCloneNetBufferList0
- FwpsFreeCloneNetBufferList0

With this flag set, **FwpsAllocateCloneNetBufferList0** will always return an **INVALID_PARAMETER** error. This may unexpectedly cause a 3rd party callout driver to fail to manage the reference count of NET_BUFFER_LISTs, causing send and receive operations to stop.

Using Proxied Connections Tracking

Article • 12/06/2022

Proxied connections tracking is supported in Windows 8 and later versions of Windows.

This WFP feature facilitates tracking of redirection “records” from the initial redirect of a connection to the final connection to the destination. WFP also allows a callout driver to redirect connections.

Proxied Connections Tracking

With the presence of multiple proxies (for example, developed by different ISVs) the connection used by one party to communicate with the final destination could in turn be redirected by a 2nd party; and that new connection could again be redirected by the original party. Without connection tracking, the original connection might never reach its final destination as it gets stuck in the infinite proxy loop.

Additions to the Data Field Identifiers to support connection tracking include:

FWPS_FIELD_Xxx_ALE_ORIGINAL_APP_ID
The full path of the original application for proxy connections. If the application has not been proxied, this path is identical to the xxx_ALE_APP_ID.

FWPS_FIELD_Xxx_PACKAGE_ID
The package identifier is a security identifier (SID) that identifies the associated AppContainer process.

Redirecting Connections

A callout driver calls the FwpsRedirectHandleCreate0 function to create a handle that can be used to redirect TCP connections.

This section includes the following topics:

Using a Redirection Handle

Querying the Redirect State

Using a Redirection Handle

Before an ALE connect redirection callout can redirect connections to a local process, it must obtain a redirect handle with the FwpsRedirectHandleCreate0 function and put the handle in the FWPS_CONNECT_REQUEST0 structure. The callout modifies the structure in the classifyFn for the ALE connect redirect layers.

The FWPS_CONNECT_REQUEST0 structure contains the following members for redirection:

Term	Description
localRedirectHandle	The redirect handle that the callout driver created by calling the FwpsRedirectHandleCreate0 function.
localRedirectContext	A callout driver context area that the callout driver allocated by calling the ExAllocatePoolWithTag function.
localRedirectContextSize	The size, in bytes, of the callout supplied context area.

After a callout driver has finished using a redirect handle, it must call the FwpsRedirectHandleDestroy0 function to destroy the handle.

Querying the Redirect State

A callout driver calls the FwpsQueryConnectionRedirectState0 function to get the redirect state of a connection. The FWPS_CONNECTION_REDIRECT_STATE enumeration is the return type for a call to the **FwpsQueryConnectionRedirectState0** function.

If the redirect status is FWPS_CONNECTION_NOT_REDIRECTED, the ALE_CONNECT_REDIRECT callout can proceed to proxy the connection.

If the redirect status is FWPS_CONNECTION_REDIRECTED_BY_SELF, the ALE_CONNECT_REDIRECT callout should return FWP_ACTION_PERMIT/FWP_ACTION_CONTINUE.

If the redirect status is FWPS_CONNECTION_REDIRECTED_BY_OTHER, the ALE_CONNECT_REDIRECT callout could proceed to proxy the connection if it does not trust the other inspector’s result.

If the redirect status is FWPS_CONNECTION_PREVIOUSLY_REDIRECTED_BY_SELF, the ALE_CONNECT_REDIRECT callout must not perform redirection even if other inspectors’ results are not acceptable. In this case, it must either permit or block the connection (at the ALE_AUTH_CONNECT layer).

Using Virtual Switch Filtering

Article • 12/15/2021

Overview of Virtual Switch Filtering

Virtual Switch Filtering is supported in Windows 8 and later versions of Windows.

This WFP feature allows filtering on fields of the MAC header, IP header, and upper protocol ports as well as virtual switch specific fields such as virtual port (VPort) and virtual machine identifier (VM ID). These layers are invoked on a per-packet basis for all packets traversing the virtual switch. These layers are accessed from a virtual switch extension filter—a type of NDIS lightweight filter (LWF) driver.

A callout driver calls the **FwpsvSwitchEventsSubscribe0** function to register callback entry points for virtual switch layer events.

The entry points for the callback notification functions are specified in an **FWPS_VSWITCH_EVENT_DISPATCH_TABLE0** structure. The callback functions that are available include:

- *FWPS_VSWITCH_FILTER_ENGINE_REORDER_CALLBACK0*
- *FWPS_VSWITCH_INTERFACE_EVENT_CALLBACK0*
- *FWPS_VSWITCH_LIFETIME_EVENT_CALLBACK0*
- *FWPS_VSWITCH_POLICY_EVENT_CALLBACK0*
- *FWPS_VSWITCH_PORT_EVENT_CALLBACK0*
- *FWPS_VSWITCH_RUNTIME_STATE_RESTORE_CALLBACK0*
- *FWPS_VSWITCH_RUNTIME_STATE_SAVE_CALLBACK0*

The **FWPS_VSWITCH_EVENT_TYPE** enumeration defines the values for the *eventType* parameter of the virtual switch notification functions.

The callout driver must eventually call **FwpsvSwitchEventsUnsubscribe0** to free the system resources.

If a callout driver returns STATUS_PENDING from a WFP notification function, WFP will return STATUS_PENDING to the OID request handler. The callout driver must call the **FwpsvSwitchNotifyComplete0** function to complete the pending operation. After the **FwpsvSwitchNotifyComplete0** call, WFP calls the **NdisFOidRequestComplete** function to complete the OID for the virtual switch.

Callbacks should not add or delete WFP filters synchronously in the context of the notification functions. In addition, if the notification function allows the callback to return STATUS_PENDING, and the callout returns STATUS_PENDING, the callout should not add or delete WFP filters before completing the notification.

WFP Virtual Switch Filter Layer and Fields

Run-time Filtering Layer Identifiers for virtual switch filtering include:

- FWPS_LAYER_INGRESS_VSWITCH_ETHERNET
- FWPS_LAYER_EGRESS_VSWITCH_ETHERNET
- FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V4
- FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V6
- FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V4
- FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V6

Data Field Identifiers for virtual switch filtering include:

- **FWPS_FIELDS_EGRESS_VSWITCH_ETHERNET**
- **FWPS_FIELDS_EGRESS_VSWITCH_TRANSPORT_V4**
- **FWPS_FIELDS_EGRESS_VSWITCH_TRANSPORT_V6**
- **FWPS_FIELDS_INGRESS_VSWITCH_ETHERNET**
- **FWPS_FIELDS_INGRESS_VSWITCH_TRANSPORT_V4**
- **FWPS_FIELDS_INGRESS_VSWITCH_TRANSPORT_V6**

Guidance For WFP Virtual Switch Callout Writers

Port 0 Traffic

For WFP virtual switch callouts, traffic from port 0 (the default port ID) is trusted and should not be filtered. This is because, generally, traffic over port 0 originates from other extensions in the driver stack and is thus treated by the data path as privileged and trusted. Virtual switch extensions will sparingly use port 0 for situations such as originating a control packet, which should not be filtered and rejected by any underlying extensions. For more information about Hyper-V extensible switch source port mofification, see Modifying a Packet's Extensible Switch Source Port Data.

Callout Matching Rules

When defining a matching rule for filtering, virtual switch callouts should not use the MAC address as a basis for comparison. MAC addresses can change at runtime, and some ports may generate traffic from multiple MAC addresses. Instead, callouts should use a more durable matching rule such as NIC ID, which will not change.

I/O Virtualization (IOV) and WFP Coexistence

WFP cannot be enabled on an IOV switch and is blocked by the OS if an attempt is made to enable it.

Enabling or Disabling WFP

Installers for WFP virtual switch callouts should not modify the WFP extension enabled state; that is, they should not enable or disable WFP itself.

Unloading a Callout Driver

Article • 12/15/2021

To unload a callout driver, the operating system calls the callout driver's unload function. For more information about how to specify a callout driver's unload function, see Specifying an Unload Function.

A callout driver's unload function guarantees that the callout driver's callouts are unregistered from the filter engine before the callout driver is unloaded from system memory. A callout driver calls either the **FwpsCalloutUnregisterById0** function or the **FwpsCalloutUnregisterByKey0** function to unregister a callout from the filter engine. A callout driver must not return from its unload function until after it has successfully unregistered all its callouts from the filter engine.

After a callout driver has unregistered all its callouts from the filter engine, it must delete the device object that it created before it originally registered its callouts. A callout driver that is based on the Windows Driver Model (WDM) calls the **IoDeleteDevice** function to delete the device object. A callout driver that is based on the Windows Driver Frameworks (WDF) calls the **WdfObjectDelete** function to delete the framework device object.

A callout driver must also destroy any packet injection handle that it previously created by calling the **FwpsInjectionHandleDestroy0** function before it returns from its unload function.

For example:

```C++
// Device object
PDEVICE_OBJECT deviceObject;

// Variable for the run-time callout identifier
UINT32 CalloutId;

// Injection handle
HANDLE injectionHandle;

// Unload function
VOID
 Unload(
    IN PDRIVER_OBJECT DriverObject
    )
{
  NTSTATUS status;
  // Unregister the callout
 status =
 FwpsCalloutUnregisterById0(
 CalloutId
      );

  // Check result
 if (status == STATUS_DEVICE_BUSY)
  {
    // For each data flow that is being processed by the
    // callout that has an associated context, clean up
    // the context and then call FwpsFlowRemoveContext0
    // to remove the context from the data flow.
    ...

    // Finish unregistering the callout
 status =
 FwpsCalloutUnregisterById0(
 CalloutId
        );
  }

  // Check status
 if (status != STATUS_SUCCESS)
  {
    // Handle error
    ...
  }

  // Delete the device object
 IoDeleteDevice(
 deviceObject
    );

  // Destroy the injection handle
 status =
 FwpsInjectionHandleDestroy0(
 injectionHandle
      );

  // Check status
 if (status != STATUS_SUCCESS)
  {
    // Handle error
    ...
  }
}
```

The previous example assumes a WDM-based callout driver. For a WDF-based callout driver, the only difference is the parameter that is passed to the callout driver's unload function and how the callout driver deletes the framework device object.

C++

```
WDFDEVICE wdfDevice;

VOID
 Unload(
    IN WDFDRIVER Driver;
    )
{

  ...

  // Delete the framework device object
 WdfObjectDelete(
 wdfDevice
    );

  ...
}
```

Callout Driver Installation

Article • 12/15/2021

This section discusses callout driver installation and includes the following topics:

INF Files for Callout Drivers

Installation of Callout Drivers

Digital Signatures for Callout Drivers

INF Files for Callout Drivers

Article • 12/15/2021

A Windows Filtering Platform callout driver is installed by a setup information file (INF) file. INF files for callout drivers contain only the following INF file sections:

INF Version Section

INF SourceDisksNames Section

INF SourceDisksFiles Section

INF DestinationDirs Section

INF DefaultInstall Section

INF DefaultInstall.Services Section

INF Strings Section

For example:

INF

```
;
; Example callout driver INF file
;

[Version]
Signature = "$Windows NT$"
Provider = %Msft%
CatalogFile = "ExampleCalloutDriver.cat"
DriverVer = 01/15/05,1.0

[SourceDisksNames]
1 = %DiskName%

[SourceDisksFiles]
ExampleCalloutDriver.sys = 1

[DestinationDirs]
DefaultDestDir = 12 ; %windir%\system32\drivers
ExampleCalloutDriver.DriverFiles = 12 ; %windir%\system32\drivers

[DefaultInstall]
OptionDesc = %Description%
CopyFiles = ExampleCalloutDriver.DriverFiles

[DefaultInstall.Services]
AddService = %ServiceName%,,ExampleCalloutDriver.Service
```

```
[DefaultUninstall]
DelFiles = ExampleCalloutDriver.DriverFiles

[DefaultUninstall.Services]
DelService = ExampleCalloutDriver,0x200 ; SPSVCINST_STOPSERVICE

[ExampleCalloutDriver.DriverFiles]
ExampleCalloutDriver.sys,,,0x00000040 ; COPYFLG_OVERWRITE_OLDER_ONLY

[ExampleCalloutDriver.Service]
DisplayName = %ServiceName%
Description = %ServiceDesc%
ServiceType = 1  ; SERVICE_KERNEL_DRIVER
StartType = 0    ; SERVICE_BOOT_START
ErrorControl = 1 ; SERVICE_ERROR_NORMAL
ServiceBinary = %12%\ExampleCalloutDriver.sys

[Strings]
Msft = "Microsoft Corporation"
DiskName = "Example Callout Driver Installation Disk"
Description = "Example Callout Driver"
ServiceName = "ExampleCalloutDriver"
ServiceDesc = "Example Callout Driver"
```

Installation of Callout Drivers

Article • 12/15/2021

A callout driver can be installed by right-clicking the driver's setup information file (INF) file and selecting **Install** from the pop-up menu that appears.

After a callout driver has been successfully installed, it can be loaded (started) by typing the following at the command prompt:

C++

```
net start drivername
```

Depending on the value specified for the **StartType** entry in the [*drivername*.Services] section of the INF file, the callout driver might be automatically loaded the next time that the system is restarted. A callout driver should usually specify zero (SERVICE_BOOT_START) for this value so that the driver is loaded and its callouts are registered before the filter engine is started. See the **INF AddService Directive** for more information.

A callout driver that is currently loaded can be unloaded (stopped) by typing the following at the command prompt:

C++

```
net stop drivername
```

A callout driver can also be installed, loaded (started), unloaded (stopped), and/or uninstalled by writing a user-mode application that calls the Win32 Service Control Manager API. For more information about Win32 service control functions, such as **CreateService**, **OpenService**, **StartService**, **ControlService**, and **DeleteService**, see the Microsoft Windows SDK.

> **Note**
>
> Starting in Windows 8 and later, callout drivers cannot be viewed or managed in the Device Manager because the Plug-and-Play (PnP) manager no longer creates device representations for non-PnP (legacy) devices.

Digital Signatures for Callout Drivers

Article • 09/12/2022

To guarantee the quality and integrity of the driver, all drivers must be digitally signed. This includes Windows Filtering Platform callout drivers.

For more information, see the following topics:

- Driver Signing
- Windows Hardware Lab Kit (HLK)

Callout Driver Programming Considerations

Article • 12/15/2021

Consider the following topics when you program a Windows Filtering Platform callout driver.

User Mode vs. Kernel Mode

If the desired filtering can be done by using the standard filtering functionality that is built in to the Windows Filtering Platform, independent software vendors (ISVs) should write user-mode management applications to configure the filter engine instead of writing kernel-mode callout drivers. A kernel-mode callout driver should only be written when you must process the network data in ways that cannot be handled by the standard, built-in filtering functionality. For information about how to write a user-mode Windows Filtering Platform management application, see the Windows Filtering Platform documentation in the Microsoft Windows SDK.

Choice of Filtering Layer

A callout driver should filter the network data at the highest possible filtering layer in the network stack. For example, if the desired filtering task can be handled at the stream layer, it should not be implemented at the network layer. For more information about recommendations of the filtering layers your driver should use to guarantee compatibility with IPsec in Windows, see Developing IPsec-Compatible Callout Drivers.

Blocking at the Application Layer Enforcement (ALE) Flow Established Layers

Usually, if a callout has been added to the filter engine at one of the *ALE flow established* filtering layers (FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 or FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6), its *classifyFn* callout function should never return FWP_ACTION_BLOCK for the action. A decision to authorize or reject a connection should not be made at one of the ALE flow established filtering layers. Such a decision should always be made at one of the other ALE filtering layers.

The only valid reason for such a *classifyFn* callout function to return FWP_ACTION_BLOCK for the action is if an error occurs that could pose a potential security risk if the established connection is not ended. In this case, returning

FWP_ACTION_BLOCK for the action closes the connection to prevent the potential security risk from being exploited.

Callout Function Execution Time

Because the filter engine typically calls a callout's callout functions at IRQL = DISPATCH_LEVEL, make sure that these functions complete their execution as quickly as possible to keep the system running efficiently. Extended execution at IRQL = DISPATCH_LEVEL can adversely affect the overall performance of the system.

Injecting Into the Receive Data Path

Callouts should recalculate IP checksums before they call packet injection functions that inject into the receive data path because the checksum in the original packet might not be correct when the packet is reassembled from IP packet fragments. There is no reliable mechanism that indicates whether a net buffer list is reassembled from fragments.

Inline Injection of TCP Packet from Transport Layers

Because of the TCP stack's locking behavior, a callout at the transport layer cannot inject a new or cloned TCP packet from the classifyFn callout function. If inline injection is desired, the callout must queue a DPC to perform the injection.

Outgoing IP Header Alignment

The MDL that describes the IP header in a net buffer list (**NET_BUFFER_CURRENT_MDL**(**NET_BUFFER_LIST_FIRST_NB**(*netBufferList*))) must be pointer-aligned when one of the packet injection functions is used to inject packet data into an outgoing path. Because an incoming packet's IP header MDL may be pointer-aligned, a callout must rebuild the IP header (if not already aligned) when injecting an incoming packet into an outgoing path.

Windows Filtering Platform Callout Drivers

Porting Packet-Processing Drivers and Apps to WFP

Article • 12/15/2021

Windows Filtering Platform (WFP) enables TCP/IP packet filtering, inspection, and modification, connection monitoring or authorization, IPsec rules and processing, and RPC filtering. Generally, you must convert your TCP/IP filtering or connection monitoring component in Windows XP and Windows Server 2003 to use a WFP user-mode application or service, a WFP kernel-mode callout driver, or both for Windows Vista and Windows Server 2008 and later. The following table lists the existing methods for packet processing in Windows XP and Windows Server 2003 and how you must change them in Windows Vista and Windows Server 2008 and later to use WFP.

Note As of Windows 8, the Transport Driver Interface (TDI) feature and Layered Service Providers (LSPs) feature are deprecated.

Existing method in Windows XPand Windows Server 2003	New method in Windows Vista and Windows Server 2008 and later
Firewall hook or filter hook driver for simple packet filtering.	User-mode application or service that uses the WFP Win32 API.
Firewall hook or filter hook driver for deep packet inspection or modification.	IP layer, Transport layer, or Application Layer Enforcement (ALE) layer callout driver and optional user-mode application or service that uses the WFP Win32 API.
Transport Driver Interface (TDI) filter driver for simple packet filtering.	User-mode application or service that uses the WFP Win32 API.
TDI filter driver for deep packet or stream inspection or modification.	Transport layer, Stream layer, and/or ALE callout driver and optional user-mode application or service that uses the WFP Win32 API

Existing method in Windows XPand Windows Server 2003	New method in Windows Vista and Windows Server 2008 and later
TDI filter driver for TCP connection or User Datagram Protocol (UDP) traffic management.	For TCP connection management: ALE callout driver and optional user-mode application or service that uses the WFP Win32 API. For TCP proxying: • In Windows Vista: Packet modification callout driver. • In Windows 7 and later: ALE_REDIRECT layer callout driver. For MAC-level filtering: • In Windows 8 and later: MAC_FRAME layer callout driver. • In Windows Vista and Windows 7: NDIS lightweight filter driver. For UDP traffic management: Stream or Datagram Data layer callout driver and optional user-mode application or service that uses the WFP Win32 API.
Windows Sockets LSP for simple packet filtering.	User-mode application or service that uses the WFP Win32 API.
Windows Sockets LSP for deep packet inspection or modification.	IP layer, ALE, Transport (such as Datagram Data), or Stream layer callout driver and optional user-mode application or service that uses the WFP Win32 API.
Network Device Interface Specification (NDIS) intermediate driver for simple packet filtering.	For IP-based filtering: User-mode application or service that uses the WFP Win32 API. For MAC-based filtering: • In Windows 8 and later: MAC_FRAME layer callout driver. • In Windows Vista and Windows 7: NDIS lightweight filter driver.

Existing method in Windows XPand Windows Server 2003	New method in Windows Vista and Windows Server 2008 and later
NDIS intermediate driver for TCP connection or UDP traffic management.	TCP connection management: ALE callout driver and optional user-mode application or service that uses the WFP Win32 API. UDP traffic management: ALE or Transport layer callout driver and optional user-mode application or service that uses the WFP Win32 API.
NDIS lightweight filter driver to perform media access control (MAC)-level filtering.	In Windows 8 and later: MAC_FRAME layer callout driver. In Windows Vista and Windows 7: NDIS lightweight filter driver.

Developing IPsec-Compatible Callout Drivers

Article • 12/15/2021

Layers That Are Compatible With IPsec

To be fully compatible with the Windows implementation of IPsec that begins with Windows Vista and Windows Server 2008, a callout driver should be registered at one of the following run-time filtering layers:

TCP Packet Filtering
Stream Layers:

- FWPS_LAYER_STREAM_V4
- FWPS_LAYER_STREAM_V6

Non-TCP and Non-Error ICMP Packet Filtering
Datagram-Data Layers:

- FWPS_LAYER_DATAGRAM_DATA_V4
- FWPS_LAYER_DATAGRAM_DATA_V6
- FWPS_LAYER_DATAGRAM_DATA_V4_DISCARD
- FWPS_LAYER_DATAGRAM_DATA_V6_DISCARD

Except for the case when incoming packets must be rebuilt before they are receive-injected from a datagram-data layer, callout drivers that are registered at these data layers are compatible with IPsec.

Layers That Are Incompatible With IPsec

Network and forwarding layers are incompatible with IPsec because at these layers IPsec traffic has not yet been decrypted or verified. IPsec policies are enforced at the transport layer, which occurs after a network layer classify operation.

The following run-time filtering layers are incompatible with IPsec because IPsec processing in Windows occurs below the following layers:

FWPS_LAYER_INBOUND_IPPACKET_V4

FWPS_LAYER_INBOUND_IPPACKET_V6

FWPS_LAYER_INBOUND_IPPACKET_V4_DISCARD

FWPS_LAYER_INBOUND_IPPACKET_V6_DISCARD

FWPS_LAYER_OUTBOUND_IPPACKET_V4

FWPS_LAYER_OUTBOUND_IPPACKET_V6

FWPS_LAYER_OUTBOUND_IPPACKET_V4_DISCARD

FWPS_LAYER_OUTBOUND_IPPACKET_V6_DISCARD

Special Considerations for Transport Layers

To make a callout driver that is registered with a transport layer (FWPS_LAYER_*XXX*_TRANSPORT_V4 or _V6) compatible with IPsec, follow these guidelines:

1. Register the callout at ALE authorize receive/accept layers (**FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4** or **FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6**) in addition to transport layers (FWPS_LAYER_*XXX*_TRANSPORT_V4 or _V6).

2. To prevent interference with internal Windows IPsec processing, register the callout at a sublayer that has a lower weight than **FWPM_SUBLAYER_UNIVERSAL**. Use the **FwpmSubLayerEnum0** function to find the sublayer's weight. For information about this function, see the Windows Filtering Platform documentation in the Microsoft Windows SDK.

3. An incoming transport packet that requires ALE classification must be inspected at the ALE authorize receive/accept layers (**FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4** or **FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6**). Such a packet must be permitted from incoming transport layers. Beginning with Windows Vista with Service Pack 1 (SP1) and Windows Server 2008, use the **FWPS_METADATA_FIELD_ALE_CLASSIFY_REQUIRED** metadata flag to determine whether the incoming packet will be indicated to the **FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4** and **FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6** filtering layers. This metadata flag replaces the **FWP_CONDITION_FLAG_REQUIRES_ALE_CLASSIFY** condition flag that was used in Windows Vista.

4. To prevent interference with internal Windows IPsec processing, do not intercept IPsec tunnel-mode traffic at transport layers if the IPsec traffic is not yet detunneled. The following code example shows how to bypass such packets.

```C++
FWPS_PACKET_LIST_INFORMATION0 packetInfo = {0};
FwpsGetPacketListSecurityInformation0(
 layerData,
    FWPS_PACKET_LIST_INFORMATION_QUERY_IPSEC |
    FWPS_PACKET_LIST_INFORMATION_QUERY_INBOUND,
    &packetInfo
    );

if (packetInfo.ipsecInformation.inbound.isTunnelMode &&
    !packetInfo.ipsecInformation.inbound.isDeTunneled)
{
 classifyOut->actionType = FWP_ACTION_PERMIT;
 goto Exit;
}
```

5. After an IPsec-protected packet is decrypted and verified at the transport layer, the AH/ESP header remains in the IP header. If such a packet has to be reinjected back into the TCP/IP stack, the IP header must be rebuilt to remove the AH/ESP header. Beginning with Windows Vista with SP1 and Windows Server 2008, you can do this by cloning the packet and calling the FwpsConstructIpHeaderForTransportPacket0 function that has the *headerIncludeHeaderSize* parameter set to the IP header size of the cloned packet.

6. At the ALE receive/accept layer, a callout can detect IPsec-protected traffic by checking whether the **FWP_CONDITION_FLAG_IS_IPSEC_SECURED** flag is set. At transport layers, a callout can detect IPsec-protected traffic by calling the FwpsGetPacketListSecurityInformation0 function and checking whether the **FWPS_PACKET_LIST_INFORMATION0** flag is set in the *queryFlags* parameter.

Working With IPsec ESP Packets

When the engine indicates decrypted encapsulating security payload (ESP) packets, it truncates them to exclude trailing ESP data. Because of the way the engine handles such packets, the MDL data in the NET_BUFFER structure does not reflect the correct packet length. The correct length can be obtained by using the NET_BUFFER_DATA_LENGTH macro to retrieve the data length of the **NET_BUFFER** structure.

Calling Other Windows Filtering Platform Functions

Article • 06/30/2022

Many of the other Windows Filtering Platform functions that are available to user-mode management applications are also available to callout drivers. This enables a callout driver to perform management tasks, such as adding filters to the filter engine. The only difference between the user-mode and kernel-mode versions of these functions is the data type that is returned. The user-mode functions return Win32 error codes, whereas the kernel-mode functions return the equivalent NTSTATUS codes.

Most of the Windows Filtering Platform management functions require a handle to an open session to the filter engine as a parameter. The following topics discuss how a callout driver can open and close a session to the filter engine.

Opening a Session to the Filter Engine

Closing a Session to the Filter Engine

For a list of the other Windows Filtering Platform functions that can be called from a callout driver, see Other Windows Filtering Platform Functions. For more information about how to use these functions, see the Windows Filtering Platform documentation in the Microsoft Windows SDK.

Opening a Session to the Filter Engine

Article • 12/15/2021

A callout driver must open a session to the filter engine to perform management tasks such as adding filters to the filter engine. A callout driver opens a session to the filter engine by calling the **FwpmEngineOpen0** function. For example:

C++

```
HANDLE engineHandle;
NTSTATUS status;

// Open a session to the filter engine
status =
 FwpmEngineOpen0(
    NULL,              // The filter engine on the local system
    RPC_C_AUTHN_WINNT, // Use the Windows authentication service
    NULL,              // Use the calling thread's credentials
    NULL,              // There are no session-specific parameters
    &engineHandle      // Pointer to a variable to receive the handle
    );
```

After a callout driver has successfully opened a session to the filter engine, it can use the returned handle to call the other Windows Filtering Platform management functions.

Closing a Session to the Filter Engine

Article • 12/15/2021

After a callout driver has performed the desired management tasks, it should close the session to the filter engine. A callout driver does this by calling the **FwpmEngineClose0** function. For example:

C++

```cpp
status =
 FwpmEngineClose0(
 engineHandle  // An handle to the open session
    );
```

Windows Filtering Platform constants

Article • 12/15/2021

This section describes constants used in Windows Filtering Platform callout drivers.

Windows Filtering Platform Callout Drivers reference

Built-in callout identifiers

Article • 12/15/2021

The identifiers for the callouts that are built into the Windows Filtering Platform are each represented by a GUID. These identifiers are defined as follows.

> ⓘ **Note**
>
> The V4 and V6 suffixes at the end of the callout identifiers indicate whether the callout is for the IPv4 network stack or the IPv6 network stack.

Built-in callout identifier	Callout description
FWPM_CALLOUT_IPSEC_INBOUND_TRANSPORT_V4 FWPM_CALLOUT_IPSEC_INBOUND_TRANSPORT_V6	Verifies that each received packet that is supposed to arrive over a transport mode security association arrives securely. This callout is applicable at the transport layer.
FWPM_CALLOUT_IPSEC_OUTBOUND_TRANSPORT_V4 FWPM_CALLOUT_IPSEC_OUTBOUND_TRANSPORT_V6	Indicates to IPsec the outbound traffic that must be secured over transport mode security associations. This callout is applicable at the transport layer.
FWPM_CALLOUT_IPSEC_INBOUND_TUNNEL_V4 FWPM_CALLOUT_IPSEC_INBOUND_TUNNEL_V6	Verifies that each received packet that is supposed to arrive over a tunnel mode security association arrives securely. This callout is applicable at the transport layer.
FWPM_CALLOUT_IPSEC_OUTBOUND_TUNNEL_V4 FWPM_CALLOUT_IPSEC_OUTBOUND_TUNNEL_V6	Indicates to IPsec the outbound traffic that must be secured over tunnel mode security associations. This callout is applicable at the transport layer.
FWPM_CALLOUT_IPSEC_FORWARD_INBOUND_TUNNEL_V4 FWPM_CALLOUT_IPSEC_FORWARD_INBOUND_TUNNEL_V6	Verifies that each received packet that is supposed to arrive over a tunnel mode security association arrives securely. This callout is applicable at the forward layer.

Built-in callout identifier	Callout description
FWPM_CALLOUT_IPSEC_FORWARD_OUTBOUND_TUNNEL_V4 FWPM_CALLOUT_IPSEC_FORWARD_OUTBOUND_TUNNEL_V6	Indicates to IPsec the outbound traffic that must be secured over a tunnel mode security association. This callout is applicable at the forward layer.
FWPM_CALLOUT_IPSEC_INBOUND_INITIATE_SECURE_V4 FWPM_CALLOUT_IPSEC_INBOUND_INITIATE_SECURE_V6	Verifies that each incoming connection that is supposed to arrive securely does so. This callout is applicable at the ALE accept layer.
FWPM_CALLOUT_IPSEC_ALE_CONNECT_V4 FWPM_CALLOUT_IPSEC_ALE_CONNECT_V6	Applies IPsec policy modifiers to client applications.
FWPM_CALLOUT_WFP_TRANSPORT_LAYER_V4_SILENT_DROP FWPM_CALLOUT_WFP_TRANSPORT_LAYER_V6_SILENT_DROP	Silently drops all incoming packets for which TCP does not have a listening endpoint. This callout is applicable at the inbound transport layer.
FWPM_CALLOUT_TCP_CHIMNEY_CONNECT_LAYER_V4 FWPM_CALLOUT_TCP_CHIMNEY_CONNECT_LAYER_V6	Enables or disables TCP chimney offload for each outgoing connection.
FWPM_CALLOUT_TCP_CHIMNEY_ACCEPT_LAYER_V4 FWPM_CALLOUT_TCP_CHIMNEY_ACCEPT_LAYER_V6	Enables or disables TCP chimney offload for each incoming connection.

Management filtering layer identifiers

Article • 12/15/2021

The management filtering layer identifiers are generally used by user-mode applications and are each represented by a GUID, which is 128 bits in size. These identifiers are defined as follows.

> ⓘ Note
>
> The V4 and V6 suffixes at the end of the layer identifiers indicate whether the layer is located in the IPv4 network stack or in the IPv6 network stack.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V6	This filtering layer is located in the receive path just after the IP header of a received packet has been parsed but before any IP header processing takes place. No IPsec decryption or reassembly has occurred.
FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD	This filtering layer is located in the receive path for processing any received packets that have been discarded at the network layer.
FWPM_LAYER_OUTBOUND_IPPACKET_V4 FWPM_LAYER_OUTBOUND_IPPACKET_V6	This filtering layer is located in the send path just before the sent packet is evaluated for fragmentation. All IP header processing is complete and all extension headers are in place. Any IPsec authentication and encryption has already occurred.
FWPM_LAYER_OUTBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_OUTBOUND_IPPACKET_V6_DISCARD	This filtering layer is located in the send path for processing any sent packets that have been discarded at the network layer.
FWPM_LAYER_IPFORWARD_V4 FWPM_LAYER_IPFORWARD_V6	This filtering layer is located in the forwarding path at the point where a received packet is forwarded.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_IPFORWARD_V4_DISCARD FWPM_LAYER_IPFORWARD_V6_DISCARD	This filtering layer is located in the forwarding path for processing any forwarded packets that have been discarded at the forward layer.
FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6	This filtering layer is located in the receive path just after a received packet's header has been parsed by the network stack at the transport layer, but before any transport layer processing takes place.
FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD	This filtering layer is located in the receive path for processing any received packets that have been discarded at the transport layer.
FWPM_LAYER_OUTBOUND_TRANSPORT_V4 FWPM_LAYER_OUTBOUND_TRANSPORT_V6	This filtering layer is located in the send path just after a sent packet has been passed to the network layer for processing but before any network layer processing takes place. This filtering layer is located at the top of the network layer instead of at the bottom of the transport layer so that any packets that are sent by third-party transports or as raw packets are filtered at this layer.
FWPM_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD	This filtering layer is located in the send path for processing any sent packets that have been discarded at the transport layer.
FWPM_LAYER_STREAM_V4 FWPM_LAYER_STREAM_V6	This filtering layer is located in the stream data path. This layer allows for processing network data on a per stream basis. At the stream layer, the network data is bidirectional.
FWPM_LAYER_STREAM_V4_DISCARD FWPM_LAYER_STREAM_V6_DISCARD	This filtering layer is reserved for future use.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_DATAGRAM_DATA_V4 FWPM_LAYER_DATAGRAM_DATA_V6	This filtering layer is located in the datagram data path. This layer allows for processing network data on a per datagram basis. At the datagram layer, the network data is bidirectional.
FWPM_LAYER_DATAGRAM_DATA_V4_DISCARD FWPM_LAYER_DATAGRAM_DATA_V6_DISCARD	This filtering layer is located in the datagram data path for processing any datagrams that have been discarded.
FWPM_LAYER_INBOUND_ICMP_ERROR_V4 FWPM_LAYER_INBOUND_ICMP_ERROR_V6	This filtering layer is located in the receive path for processing received ICMP messages for the transport protocol.
FWPM_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD	This filtering layer is located in the receive path for processing received ICMP messages that have been discarded.
FWPM_LAYER_OUTBOUND_ICMP_ERROR_V4 FWPM_LAYER_OUTBOUND_ICMP_ERROR_V6	This filtering layer is located in the send path for processing sent ICMP messages for the transport protocol.
FWPM_LAYER_OUTBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_OUTBOUND_ICMP_ERROR_V6_DISCARD	This filtering layer is located in the send path for processing sent ICMP messages that have been discarded.
FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6	This filtering layer allows for authorizing connect requests for outgoing TCP connections, as well as authorizing outgoing non-TCP traffic based on the first packet sent.
FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD	This filtering layer allows for processing connect requests for outgoing TCP connections that have been discarded, as well as processing authorizations for outgoing non-TCP traffic that have been discarded.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6	This filtering layer allows for notification of when a TCP connection has been established, or when non-TCP traffic has been authorized.
FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD	This filtering layer allows for processing when an established TCP connection has been discarded at the flow established layer, as well as when authorized non-TCP traffic has been discarded at the flow established layer.
FWPM_LAYER_ALE_AUTH_LISTEN_V4 FWPM_LAYER_ALE_AUTH_LISTEN_V6	This filtering layer allows for authorizing TCP listen requests.
FWPM_LAYER_ALE_AUTH_LISTEN_V4_DISCARD FWPM_LAYER_ALE_AUTH_LISTEN_V6_DISCARD	This filtering layer allows for processing TCP listen requests that have been discarded.
FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6	This filtering layer allows for authorizing accept requests for incoming TCP connections, as well as authorizing incoming non-TCP traffic based on the first packet received.
FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD	This filtering layer allows for processing accept requests for incoming TCP connections that have been discarded, as well as processing authorizations for incoming non-TCP traffic that have been discarded.
FWPM_LAYER_ALE_AUTH_ROUTE_V4 FWPM_LAYER_ALE_AUTH_ROUTE_V6	This filtering layer allows for inspecting and filtering the route and path parameters of bind and connect requests.
FWPM_LAYER_ALE_ENDPOINT_CLOSURE_V4 FWPM_LAYER_ALE_ENDPOINT_CLOSURE_V6	This filtering layer is used as an opportunity to reclaim resources allocated by the callout driver in any of the ALE_AUTH_CONNECT or ALE_AUTH_RECV_ACCEPT layers.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6	This filtering layer allows for authorizing transport port assignments, bind requests, promiscuous mode requests, and raw mode requests.
FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4_DISCARD FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD	This filtering layer allows for processing the following discarded items: transport port assignments, bind requests, promiscuous mode requests, and raw mode requests.
FWPM_LAYER_ALE_RESOURCE_RELEASE_V4 FWPM_LAYER_ALE_RESOURCE_RELEASE_V6	This filtering layer is used as an opportunity to reclaim resources allocated by the callout driver in any of the ALE_RESOURCE_ASSIGNMENT layers.
FWPM_LAYER_IPSEC_KM_DEMUX_V4 FWPM_LAYER_IPSEC_KM_DEMUX_V6	This filtering layer is used to determine which keying modules are invoked when the local system is the initiator. This is a user-mode filtering layer.
FWPM_LAYER_IPSEC_V4 FWPM_LAYER_IPSEC_V6	This filtering layer allows the keying module to look up quick-mode policy information when negotiating quick-mode security associations. This is a user-mode filtering layer.
FWPM_LAYER_IKEEXT_V4 FWPM_LAYER_IKEEXT_V6	This filtering layer allows the IKE and authenticated IP modules to look up main-mode policy information when negotiating main-mode security associations. This is a user-mode filtering layer.
FWPM_LAYER_RPC_UM	This filtering layer allows for inspecting the RPC data fields that are available in user mode. This is a user-mode filtering layer.
FWPM_LAYER_RPC_EPMAP	This filtering layer allows for inspecting the RPC data fields that are available in user mode during endpoint resolution. This is a user-mode filtering layer.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_RPC_EP_ADD	This filtering layer allows for inspecting the RPC data fields that are available in user mode when a new endpoint is added. This is a user-mode filtering layer.
FWPM_LAYER_RPC_PROXY_CONN	This filtering layer allows for inspecting RpcProxy connection requests. This is a user-mode filtering layer.
FWPM_LAYER_RPC_PROXY_IF	This filtering layer allows for inspecting the interface used for RpcProxy connections. This is a user-mode filtering layer.
FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET	This filtering layer allows for inspecting the MAC frame data at the inbound lower (to the NDIS protocol driver) layer. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET	This filtering layer allows for inspecting the MAC frame data at the outbound upper (to the NDIS protocol driver) layer. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE	This filtering layer allows for inspecting the MAC frame data at the inbound lower (to the NDIS miniport driver) layer. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE	This filtering layer allows for inspecting the MAC frame data at the outbound lower (to the NDIS miniport driver) layer. **Note**: Available only on Windows 8 and later.

Management filtering layer identifier	Filtering layer description
FWPM_LAYER_INGRESS_VSWITCH_ETHERNET	This filtering layer allows for inspecting the ingress 802.3 data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_EGRESS_VSWITCH_ETHERNET	This filtering layer allows for inspecting the egress 802.3 data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_INGRESS_VSWITCH_TRANSPORT_V4 FWPM_LAYER_INGRESS_VSWITCH_TRANSPORT_V6	This filtering layer allows for inspecting the ingress transport data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPM_LAYER_EGRESS_VSWITCH_TRANSPORT_V4 FWPM_LAYER_EGRESS_VSWITCH_TRANSPORT_V6	This filtering layer allows for inspecting the egress transport data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.

Run-time filtering layer identifiers

Article • 12/15/2021

The run-time filtering layer identifiers are used by kernel-mode callout drivers and are each represented by a locally unique identifier (LUID), which is 64 bits in size. These identifiers are constant values in the FWPS_BUILTIN_LAYERS enumeration that is defined in Fwpsk.h. These identifiers are defined as follows:

> ⓘ Note
>
> The V4 and V6 suffixes at the end of the run-time layer identifiers indicate whether the layer is located in the IPv4 network stack or in the IPv6 network stack.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_INBOUND_IPPACKET_V4 FWPS_LAYER_INBOUND_IPPACKET_V6	This filtering layer is located in the receive path just after the IP header of a received packet has been parsed but before any IP header processing takes place. No IPsec decryption or reassembly has occurred.
FWPS_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPS_LAYER_INBOUND_IPPACKET_V6_DISCARD	This filtering layer is located in the receive path for processing any received packets that have been discarded at the network layer.
FWPS_LAYER_OUTBOUND_IPPACKET_V4 FWPS_LAYER_OUTBOUND_IPPACKET_V6	This filtering layer is located in the send path just before the sent packet is evaluated for fragmentation. All IP header processing is complete and all extension headers are in place. Any IPsec authentication and encryption has already occurred.
FWPS_LAYER_OUTBOUND_IPPACKET_V4_DISCARD FWPS_LAYER_OUTBOUND_IPPACKET_V6_DISCARD	This filtering layer is located in the send path for processing any sent packets that have been discarded at the network layer.
FWPS_LAYER_IPFORWARD_V4 FWPS_LAYER_IPFORWARD_V6	This filtering layer is located in the forwarding path at the point where a received packet is forwarded.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_IPFORWARD_V4_DISCARD FWPS_LAYER_IPFORWARD_V6_DISCARD	This filtering layer is located in the forwarding path for processing any forwarded packets that have been discarded at the forward layer.
FWPS_LAYER_INBOUND_TRANSPORT_V4 FWPS_LAYER_INBOUND_TRANSPORT_V6	This filtering layer is located in the receive path just after a received packet's header has been parsed by the network stack at the transport layer, but before any transport layer processing takes place.
FWPS_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPS_LAYER_INBOUND_TRANSPORT_V6_DISCARD	This filtering layer is located in the receive path for processing any received packets that have been discarded at the transport layer.
FWPS_LAYER_OUTBOUND_TRANSPORT_V4 FWPS_LAYER_OUTBOUND_TRANSPORT_V6	This filtering layer is located in the send path just after a sent packet has been passed to the network layer for processing but before any network layer processing takes place. This filtering layer is located at the top of the network layer instead of at the bottom of the transport layer so that any packets that are sent by third-party transports or as raw packets are filtered at this layer.
FWPS_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPS_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD	This filtering layer is located in the send path for processing any sent packets that have been discarded at the transport layer.
FWPS_LAYER_STREAM_V4 FWPS_LAYER_STREAM_V6	This filtering layer is located in the stream data path. This layer allows for processing network data on a per stream basis. At the stream layer, the network data is bidirectional.
FWPS_LAYER_STREAM_V4_DISCARD FWPS_LAYER_STREAM_V6_DISCARD	This filtering layer is reserved for future use.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_DATAGRAM_DATA_V4 FWPS_LAYER_DATAGRAM_DATA_V6	This filtering layer is located in the datagram data path. This layer allows for processing network data on a per datagram basis. At the datagram layer, the network data is bidirectional.
FWPS_LAYER_DATAGRAM_DATA_V4_DISCARD FWPS_LAYER_DATAGRAM_DATA_V6_DISCARD	This filtering layer is located in the datagram data path for processing any datagrams that have been discarded.
FWPS_LAYER_INBOUND_ICMP_ERROR_V4 FWPS_LAYER_INBOUND_ICMP_ERROR_V6	This filtering layer is located in the receive path for processing received ICMP messages for the transport protocol.
FWPS_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPS_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD	This filtering layer is located in the receive path for processing received ICMP messages that have been discarded.
FWPS_LAYER_OUTBOUND_ICMP_ERROR_V4 FWPS_LAYER_OUTBOUND_ICMP_ERROR_V6	This filtering layer is located in the send path for processing sent ICMP messages for the transport protocol.
FWPS_LAYER_OUTBOUND_ICMP_ERROR_V4_DISCARD FWPS_LAYER_OUTBOUND_ICMP_ERROR_V6_DISCARD	This filtering layer is located in the send path for processing sent ICMP messages that have been discarded.
FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V4 FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V6	This filtering layer allows for authorizing transport port assignments, bind requests, promiscuous mode requests, and raw mode requests.
FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V4_DISCARD FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD	This filtering layer allows for processing the following discarded items: transport port assignments, bind requests, promiscuous mode requests, and raw mode requests.
FWPS_LAYER_ALE_AUTH_LISTEN_V4 FWPS_LAYER_ALE_AUTH_LISTEN_V6	This filtering layer allows for authorizing TCP listen requests.
FWPS_LAYER_ALE_AUTH_LISTEN_V4_DISCARD FWPS_LAYER_ALE_AUTH_LISTEN_V6_DISCARD	This filtering layer allows for processing TCP listen requests that have been discarded.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6	This filtering layer allows for authorizing accept requests for incoming TCP connections, as well as authorizing incoming non-TCP traffic based on the first packet received.
FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD	This filtering layer allows for processing accept requests for incoming TCP connections that have been discarded, as well as processing authorizations for incoming non-TCP traffic that have been discarded.
FWPS_LAYER_ALE_AUTH_CONNECT_V4 FWPS_LAYER_ALE_AUTH_CONNECT_V6	This filtering layer allows for authorizing connect requests for outgoing TCP connections, as well as authorizing outgoing non-TCP traffic based on the first packet sent.
FWPS_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPS_LAYER_ALE_AUTH_CONNECT_V6_DISCARD	This filtering layer allows for processing connect requests for outgoing TCP connections that have been discarded, as well as processing authorizations for outgoing non-TCP traffic that have been discarded.
FWPS_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPS_LAYER_ALE_FLOW_ESTABLISHED_V6	This filtering layer allows for notification of when a TCP connection has been established, or when non-TCP traffic has been authorized.
FWPS_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPS_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD	This filtering layer allows for processing when an established TCP connection has been discarded at the flow established layer, as well as when authorized non-TCP traffic has been discarded at the flow established layer.
FWPS_LAYER_RESERVED1_V4 FWPS_LAYER_RESERVED1_V6	This filtering layer is not supported.
FWPS_LAYER_NAME_RESOLUTION_CACHE_V4 FWPS_LAYER_NAME_RESOLUTION_CACHE_V6	This filtering layer allows for querying the names recently resolved by the system.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_ALE_RESOURCE_RELEASE_V4 FWPS_LAYER_ALE_RESOURCE_RELEASE_V6	This filtering layer is used as an opportunity to reclaim resources allocated by the callout driver in any of the ALE_RESOURCE_ASSIGNMENT layers.
FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V4 FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V6	This filtering layer is used as an opportunity to reclaim resources allocated by the callout driver in any of the ALE_AUTH_CONNECT or ALE_AUTH_RECV_ACCEPT layers.
FWPS_LAYER_ALE_CONNECT_REDIRECT_V4 FWPS_LAYER_ALE_CONNECT_REDIRECT_V6	This filtering layer allows for the redirecting of connect requests to a different IPV4/ IPV6 address and TCP/UDP port.
FWPS_LAYER_ALE_BIND_REDIRECT_V4 FWPS_LAYER_ALE_BIND_REDIRECT_V6	This filtering layer allows for the redirecting of bind requests to a different local IPV4/ IPV6 address and/or local TCP/UDP port.
FWPS_LAYER_INBOUND_MAC_FRAME_ETHERNET	This filtering layer allows for inspecting the MAC frame data at the inbound lower (to the NDIS protocol driver) layer. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_OUTBOUND_MAC_FRAME_ETHERNET	This filtering layer allows for inspecting the MAC frame data at the outbound upper (to the NDIS protocol driver) layer. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_INBOUND_MAC_FRAME_NATIVE	This filtering layer allows for inspecting the MAC frame data at the inbound lower (to the NDIS miniport driver) layer. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_OUTBOUND_MAC_FRAME_NATIVE	This filtering layer allows for inspecting the MAC frame data at the outbound lower (to the NDIS miniport driver) layer. **Note**: Available only on Windows 8 and later.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_INGRESS_VSWITCH_ETHERNET	This filtering layer allows for inspecting the ingress 802.3 data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_EGRESS_VSWITCH_ETHERNET	This filtering layer allows for inspecting the egress 802.3 data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V4 FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V6	This filtering layer allows for inspecting the ingress transport data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V4 FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V6	This filtering layer allows for inspecting the egress transport data of the Hyper-V extensible switch. **Note**: Available only on Windows 8 and later.
FWPS_LAYER_STREAM_PACKET_V4 FWPS_LAYER_STREAM_PACKET_V6	This filtering layer allows for inspection of network data on a per-TCP packet basis, including handshake and flow control exchanges. At the stream packet layer, the network data is bidirectional.
FWPS_LAYER_IPSEC_KM_DEMUX_V4 FWPS_LAYER_IPSEC_KM_DEMUX_V6	This filtering layer is used to determine which keying modules are invoked when the local system is the initiator. This is a user-mode filtering layer.
FWPS_LAYER_IPSEC_V4 FWPS_LAYER_IPSEC_V6	This filtering layer allows the keying module to look up quick-mode policy information when negotiating quick-mode security associations. This is a user-mode filtering layer.

Run-time filtering layer identifier	Filtering layer description
FWPS_LAYER_IKEEXT_V4 FWPS_LAYER_IKEEXT_V6	This filtering layer allows the IKE and authenticated IP modules to look up main-mode policy information when negotiating main-mode security associations. This is a user-mode filtering layer.
FWPS_LAYER_RPC_UM	This filtering layer allows for inspecting the RPC data fields that are available in user mode. This is a user-mode filtering layer.
FWPS_LAYER_RPC_EPMAP	This filtering layer allows for inspecting the RPC data fields that are available in user mode during endpoint resolution. This is a user-mode filtering layer.
FWPS_LAYER_RPC_EP_ADD	This filtering layer allows for inspecting the RPC data fields that are available in user mode when a new endpoint is added. This is a user-mode filtering layer.
FWPS_LAYER_RPC_PROXY_CONN	This filtering layer allows for inspecting RpcProxy connection requests. This is a user-mode filtering layer.
FWPS_LAYER_RPC_PROXY_IF	This filtering layer allows for inspecting the interface used for RpcProxy connections. This is a user-mode filtering layer.
FWPS_LAYER_KM_AUTHORIZATION	This filtering layer allows for authorizing security association establishment.

Each run-time layer identifier has an associated run-time data field identifier that represents a set of constant values. These data field identifiers are declared as FWPS_FIELDS_XXX enumerations in Fwpsk.h. For more information, see Data Field Identifiers.

Filtering condition identifiers

Article • 12/15/2021

The filtering condition identifiers are each represented by a GUID. These identifiers are described in the following table.

Filtering condition identifier	Description
FWPM_CONDITION_ARRIVAL_INTERFACE_INDEX	The index of the arrival network interface, as enumerated by the network stack. WFP uses the Arrival interface to match this condition. The Arrival Interface is the first interface the packet sees before entering the IP stack inbound from the network, before weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an inbound condition. This means that WFP will use an empty value on this condition when reauthorizing an inbound connection on a response outbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of arrival interface conditions, the next hop class of interface conditions will have a valid interface on outbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_ARRIVAL_INTERFACE_TYPE	The type of the arrival network interface, as defined by the Internet Assigned Numbers Authority (IANA). For more information, see IANAifType-MIB Definitions ↗ . WFP uses the Arrival interface to match this condition. The Arrival Interface is the first interface the packet sees before entering the IP stack inbound from the network, before weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an inbound condition. This means that WFP will use an empty value on this condition when reauthorizing an inbound connection on a response outbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of arrival interface conditions, the next hop class of interface conditions will have a valid interface on outbound packets. Note that this is vailable only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_ARRIVAL_TUNNEL_TYPE	The encapsulation method used by a tunnel if the IfType member of the IP_ADAPTER_ADDRESSES structure is IF_TYPE_TUNNEL. The tunnel type is defined by the IANA. For more information, see IANAifType-MIB Definitions and the Windows SDK IP Helper documentation. WFP uses the Arrival interface to match this condition. The Arrival Interface is the first interface the packet sees before entering the IP stack inbound from the network, before weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an inbound condition. This means that WFP will use an empty value on this condition when reauthorizing an inbound connection on a response outbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of arrival interface conditions, the next hop class of interface conditions will have a valid interface on outbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_IP_ARRIVAL_INTERFACE	The LUID for the network interface that is associated with the arrival IP address. WFP uses the Arrival interface to match this condition. The Arrival Interface is the first interface the packet sees before entering the IP stack inbound from the network, before weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an inbound condition. This means that WFP will use an empty value on this condition when reauthorizing an inbound connection on a response outbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of arrival interface conditions, the next hop class of interface conditions will have a valid interface on outbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_NEXTHOP_INTERFACE_INDEX	The index of the arrival network interface, as enumerated by the network stack. WFP uses the Next Hop interface to match this condition. The Next Hop Interface is the last interface the packet sees before leaving the IP stack outbound towards the network, after weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an outbound condition. This means that WFP will use an empty value on this condition when reauthorizing an outbound connection on a response inbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of next hop interface conditions, the arrival class of interface conditions will have a valid interface on inbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_NEXTHOP_INTERFACE_TYPE	The type of the arrival network interface, as defined by the Internet Assigned Numbers Authority (IANA). For more information, see IANAifType-MIB Definitions . WFP uses the Next Hop interface to match this condition. The Next Hop Interface is the last interface the packet sees before leaving the IP stack outbound towards the network, after weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an outbound condition. This means that WFP will use an empty value on this condition when reauthorizing an outbound connection on a response inbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of next hop interface conditions, the arrival class of interface conditions will have a valid interface on inbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_NEXTHOP_TUNNEL_TYPE	The encapsulation method used by a tunnel if the **IfType** member of the **IP_ADAPTER_ADDRESSES** structure is IF_TYPE_TUNNEL. The tunnel type is defined by the IANA. For more information, see IANAifType-MIB Definitions and the Windows SDK IP Helper documentation. WFP uses the Next Hop interface to match this condition. The Next Hop Interface is the last interface the packet sees before leaving the IP stack outbound towards the network, after weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an outbound condition. This means that WFP will use an empty value on this condition when reauthorizing an outbound connection on a response inbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of next hop interface conditions, the arrival class of interface conditions will have a valid interface on inbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_IP_NEXTHOP_INTERFACE	The LUID for the network interface that is associated with the arrival IP addres WFP uses the Next Hop interface to match this condition. The Next Hop Interface is the last interface the packet sees before leaving the IP stack outbound towards the network, after weak-host or forwarding are performed. This condition is asymmetric for reauthorization purposes, as it is intrinsically an outbound condition. This means that WFP will use an empty value on this condition when reauthorizing an outbound connection on a response inbound packet. To handle reauthorization a second filter must be used. This second filter can either permit or block the empty values, or use a different condition that will have a valid value for such circumstance. In the case of next hop interface conditions, the arrival class of interface conditions will have a valid interface on inbound packets. Note that this is available only in Windows Server 2008 R2, Windows 7, and later versions of Windows.
FWPM_CONDITION_IP_LOCAL_ADDRESS	The local IP address.
FWPM_CONDITION_IP_REMOTE_ADDRESS	The remote IP address.
FWPM_CONDITION_IP_SOURCE_ADDRESS	The source IP address for forwarded packets.
FWPM_CONDITION_IP_DESTINATION_ADDRESS	The destination IP address for forwarded packets.

Filtering condition identifier	Description
FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE	The local IP address type. The possible condition values are: - NlatUnspecified - NlatUnicast - NlatAnycast - NlatMulticast - NlatBroadcast
FWPM_CONDITION_IP_DESTINATION_ADDRESS_TYPE	The destination IP address type. The possible condition values are: - NlatUnspecified - NlatUnicast - NlatAnycast - NlatMulticast - NlatBroadcast
FWPM_CONDITION_IP_LOCAL_INTERFACE	The LUID for the network interface associated with the local IP address.
FWPM_CONDITION_IP_FORWARD_INTERFACE	The LUID for the network interface on which the packet being forwarded is to be sent out.
FWPM_CONDITION_IP_PROTOCOL	The IP protocol number, as specified in RFC 1700 .
FWPM_CONDITION_IP_LOCAL_PORT	The local transport protocol port number.
FWPM_CONDITION_IP_REMOTE_PORT	The remote transport protocol port number.
FWPM_CONDITION_ICMP_TYPE	The ICMP type field, as specified in RFC 792 .
FWPM_CONDITION_ICMP_CODE	The ICMP code field, as specified in RFC 792 .

Filtering condition identifier	Description
FWPM_CONDITION_EMBEDDED_LOCAL_ADDRESS_TYPE	The local IP address type that is embedded in the ICMP packet. The possible condition values are: - NlatUnspecified - NlatUnicast - NlatAnycast - NlatMulticast - NlatBroadcast
FWPM_CONDITION_EMBEDDED_REMOTE_ADDRESS	The remote IP address that is embedded in the ICMP packet.
FWPM_CONDITION_EMBEDDED_PROTOCOL	The IP protocol number that is embedded in the ICMP packet, as specified in RFC 1700 .
FWPM_CONDITION_EMBEDDED_LOCAL_PORT	The local transport protocol port number that is embedded in the ICMP packet.
FWPM_CONDITION_EMBEDDED_REMOTE_PORT	The remote transport protocol port number that is embedded in the ICMP packet.
FWPM_CONDITION_FLAGS	A bitwise OR of a combination of filtering condition flags. For information about the possible flags, see Filtering Condition Flags.

Filtering condition identifier	Description
FWPM_CONDITION_DIRECTION	The direction of the datagram traffic or data flow. The possible condition values are: - FWP_DIRECTION_INBOUND - FWP_DIRECTION_OUTBOUND In datagram data layers and stream packet layers, this condition specifies the direction of the packet. In stream layers and ALE flow established layers, this condition specifies the direction of the connection (for example, when a local application initiates the connection, an inbound packet has FWPM_CONDITION_DIRECTION set to FWP_DIRECTION_OUTBOUND).
FWPM_CONDITION_INTERFACE_INDEX	The index of the network interface, as enumerated by the network stack.
FWPM_CONDITION_INTERFACE_TYPE	The bus type of the network interface.
FWPM_CONDITION_SUB_INTERFACE_INDEX	The index of the logical network interface, as enumerated by the network stack.
FWPM_CONDITION_SOURCE_INTERFACE_INDEX	The index of the source network interface for forwarded packets, as enumerated by the network stack.
FWPM_CONDITION_SOURCE_SUB_INTERFACE_INDEX	The index of the source logical network interface for forwarded packets, as enumerated by the network stack.
FWPM_CONDITION_DESTINATION_INTERFACE_INDEX	The index of the destination network interface for forwarded packets, as enumerated by the network stack.

Filtering condition identifier	Description
FWPM_CONDITION_DESTINATION_SUB_INTERFACE_INDEX	The index of the destination logical network interface for forwarded packets, as enumerated by the network stack.
FWPM_CONDITION_ALE_APP_ID	The full path of the application.
FWPM_CONDITION_ALE_USER_ID	The identification of the local user.
FWPM_CONDITION_ALE_REMOTE_USER_ID	The identification of the remote user.
FWPM_CONDITION_ALE_REMOTE_MACHINE_ID	The identification of the remote machine.
FWPM_CONDITION_ALE_PROMISCUOUS_MODE	The raw socket mode that is allowed or denied. The possible condition values are: - SIO_RCVALL - SIO_RCVALL_IGMPMCAST - SIO_RCVALL_MCAST For a description of these raw socket modes, see WSAIoctl in the Microsoft Windows SDK documentation.
FWPM_CONDITION_ALE_SIO_FIREWALL_SYSTEM_PORT	Reserved for internal use.
FWPM_CONDITION_ALE_NAP_CONTEXT	Reserved for internal use.
FWPM_CONDITION_REMOTE_USER_TOKEN	The identification of the remote user.
FWPM_CONDITION_RPC_IF_UUID	The UUID of the RPC interface.
FWPM_CONDITION_RPC_IF_VERSION	The version of the RPC interface.
FWPM_CONDITION_RCP_IF_FLAG	Reserved for internal use.
FWPM_CONDITION_DCOM_APP_ID	The identification of the COM application.
FWPM_CONDITION_IMAGE_NAME	The name of the application.

Filtering condition identifier	Description
FWPM_CONDITION_RPC_PROTOCOL	The RPC protocol. The possible condition values are: - RPC_PROTSEQ_TCP - RPC_PROTSEQ_HTTP - RPC_PROTSEQ_NMP
FWPM_CONDITION_RPC_AUTH_TYPE	The authentication service type. For more information about authentication service types, see Authentication-Service Constants in the RPC section of the Windows SDK documentation.
FWPM_CONDITION_RPC_AUTH_LEVEL	The authentication service level. For more information about authentication service levels, see Authentication-Level Constants in the RPC section of the Windows SDK documentation.
FWPM_CONDITION_SEC_ENCRYPT_ALGORITHM	The certificate based security service provider interface (SSPI) encryption algorithm.
FWPM_CONDITION_SEC_KEY_SIZE	The certificate based security service provider interface (SSPI) encryption key size.
FWPM_CONDITION_IP_LOCAL_ADDRESS_V4	The local IPv4 address.
FWPM_CONDITION_IP_LOCAL_ADDRESS_V6	The local IPv6 address.
FWPM_CONDITION_PIPE	The name of the remote named pipe.
FWPM_CONDITION_IP_REMOTE_ADDRESS_V4	The remote IPv4 address.
FWPM_CONDITION_IP_REMOTE_ADDRESS_V6	The remote IPv6 address.
FWPM_CONDITION_PROCESS_WITH_RPC_IF_UUID	The UUID of the process with the RPC interface.
FWPM_CONDITION_RPC_EP_VALUE	Reserved for internal use.
FWPM_CONDITION_RPC_EP_FLAGS	Reserved for internal use.
FWPM_CONDITION_CLIENT_TOKEN	The identification of the client when using RpcProxy.

Filtering condition identifier	Description
FWPM_CONDITION_RPC_SERVER_NAME	The name of the RPC server when using RpcProxy.
FWPM_CONDITION_RPC_SERVER_PORT	The port on the RPC server when using RpcProxy.
FWPM_CONDITION_RPC_PROXY_AUTH_TYPE	The RPC proxy authentication service type. For more information about authentication service types, see Authentication-Service Constants in the RPC section of the Windows SDK documentation.
FWPM_CONDITION_TUNNEL_TYPE	The encapsulation method used by a tunnel.
FWPM_CONDITION_CLIENT_CERT_KEY_LENGTH	The secure socket layer (SSL) key length in the client certificate.
FWPM_CONDITION_CLIENT_CERT_OID	The object identifier (OID) in the client certificate.
FWPM_CONDITION_INTERFACE_MAC_ADDRESS	The physical address of the sending or receiving network interface. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_LOCAL_ADDRESS	The physical address of the local network interface. For inbound traffic this is the destination MAC address in the frame. For outbound traffic this is the source MAC address of the frame. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_MAC_REMOTE_ADDRESS	The physical address of the remote network interface. For inbound traffic this is the source MAC address in the frame. For outbound traffic this is the destination MAC address of the frame. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_ETHER_TYPE	The type indicated in the MAC frame. This value is 0x800 for IPv4 traffic, 0x86DD for IPv6 traffic or, 0x806 for ARP traffic. All of the possible values are defined as NDIS_ETH_TYPE_Xxx in ntddndis.h.
FWPM_CONDITION_VLAN_ID	The identifier of the VLAN in the ETHERNET SNAP header. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_NDIS_PORT	The port number identifying a miniport adapter port. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_NDIS_MEDIA_TYPE	The type of the NDIS medium specified as one of the NDIS_MEDIUM enumeration values. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_NDIS_PHYSICAL_MEDIA_TYPE	The type of the physical medium for the communicating interface specified as one of the NDIS_PHYSICAL_MEDIUM enumeration values. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_L2_FLAGS	A bitwise OR of a combination of filtering condition flags for the MAC layers. For information about the possible flags, see Filtering Condition L2 Flags. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_LOCAL_ADDRESS_TYPE	The Datalink type of the local MAC address. This is one of the values that are defined in the DL_ADDRESS_TYPE enumeration in FwpmTypes.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_REMOTE_ADDRESS_TYPE	The Datalink type of the remote MAC address. This is one of the values that are defined in the DL_ADDRESS_TYPE enumeration in FwpmTypes.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_INTERFACE	The LUID for the network interface that is associated with the local MAC address. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_ALE_PACKAGE_ID	The security identifier (SID) of the AppContainer restricted package. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_SOURCE_ADDRESS	The physical address of the network interface that created the MAC frame. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_MAC_DESTINATION_ADDRESS	The physical address of the network interface to which the frame is destined. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_SOURCE_ADDRESS_TYPE	The Datalink type of the MAC Address for the interface that created the frame. This is one of the values that are defined in the DL_ADDRESS_TYPE enumeration in FwpmTypes.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_MAC_DESTINATION_ADDRESS_TYPE	The Datalink type of the MAC Address for the interface to which the frame is destined. This is one of the values that are defined in the DL_ADDRESS_TYPE enumeration in FwpmTypes.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_IP_SOURCE_PORT	The transport protocol source port number. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_IP_DESTINATION_PORT	The transport protocol destination port number. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_VSWITCH_ID	The GUID of the virtual switch. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_VSWITCH_NETWORK_TYPE	The type of network that is associated with the virtual switch. This is one of the values that are defined in the FWP_VSWITCH_NETWORK_TYPE enumeration in FwpTypes.h. **Note** Supported in Windows 8 and later versions of Windows.
FWPM_CONDITION_VSWITCH_SOURCE_INTERFACE_ID	The GUID of the interface of the virtual switch that created the frame. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_VSWITCH_DESTINATION_INTERFACE_ID	The GUID of the interface of the virtual switch to which the frame is destined. **Note** Supported in Windows 8 and later versions of Windows.
FWPM_CONDITION_VSWITCH_SOURCE_INTERFACE_TYPE	The type of the virtual switch interface that created the frame. This is one of the values that are defined in the NDIS_NIC_SWITCH_TYPE enumeration in Ntddndis.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_VSWITCH_DESTINATION_INTERFACE_TYPE	The type of the virtual switch interface to which the frame is destined. This is one of the values that are defined in the NDIS_NIC_SWITCH_TYPE enumeration in Ntddndis.h. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_VSWITCH_SOURCE_VM_ID	Unique identifier of the vSwitch source virtual machine. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition identifier	Description
FWPM_CONDITION_VSWITCH_DESTINATION_VM_ID	Unique identifier of the vSwitch destination virtual machine. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_VSWITCH_TENANT_NETWORK_ID	Unique identifier for the vSwitch network. Cannot be used in conjunction with VLAN_IDs. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_ALE_PACKAGE_ID	The security identifier (SID) of an app container. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_ALE_ORIGINAL_APP_ID	The original full path of the application before alteration from proxying. Note that if proxying is not involved, then this will be the same as the FWPM_CONDITION_ALE_APP_ID. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.
FWPM_CONDITION_QM_MODE	The quick mode (QM) mode. **Note** Supported in Windows 8, Windows Server 2012, and later versions of Windows.

Filtering condition flags

Article • 12/06/2022

The filtering condition flags are each represented by a bit field. These flags are defined as follows:

> ⓘ **Note**
>
> This topic contains filtering condition flags for kernel mode WFP callout drivers. For information about filtering condition flags that are shared between user mode and kernel mode, or if you are looking for information about a flag that isn't listed here, see **Filtering Condition Flags**.

Filtering condition flag	Description
FWP_CONDITION_FLAG_IS_LOOPBACK 0x00000001	Indicates that the network traffic is loopback traffic. This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V6 FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD FWPM_LAYER_OUTBOUND_IPPACKET_V4 FWPM_LAYER_OUTBOUND_IPPACKET_V6 FWPM_LAYER_OUTBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_OUTBOUND_IPPACKET_V6_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V4 FWPM_LAYER_OUTBOUND_TRANSPORT_V6 FWPM_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_DATAGRAM_DATA_V4 FWPM_LAYER_DATAGRAM_DATA_V6 FWPM_LAYER_DATAGRAM_DATA_V4_DISCARD FWPM_LAYER_DATAGRAM_DATA_V6_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V4 FWPM_LAYER_INBOUND_ICMP_ERROR_V6 FWPM_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD FWPM_LAYER_OUTBOUND_ICMP_ERROR_V4 FWPM_LAYER_OUTBOUND_ICMP_ERROR_V6 FWPM_LAYER_OUTBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_OUTBOUND_ICMP_ERROR_V6_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD
FWP_CONDITION_FLAG_IS_IPSEC_SECURED	Indicates that the network traffic is protected by IPsec.

0x00000002	This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD
FWP_CONDITION_FLAG_IS_REAUTHORIZE 0x00000004	Indicates a policy change (as opposed to a new connection). This flag is applicable at the following filtering layers: FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD This flag is also applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_ALE_BIND_REDIRECT_V4 FWPM_LAYER_ALE_BIND_REDIRECT_V6
FWP_CONDITION_FLAG_IS_WILDCARD_BIND 0x00000008	Indicates that the application specified a wildcard address when binding to a local network address. This flag is applicable at the following filtering layers: FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4_DISCARD FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD
FWP_CONDITION_FLAG_IS_RAW_ENDPOINT 0x00000010	Indicates that the local endpoint that is sending and receiving traffic is a raw endpoint. This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V4 FWPM_LAYER_OUTBOUND_TRANSPORT_V6 FWPM_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_DATAGRAM_DATA_V4 FWPM_LAYER_DATAGRAM_DATA_V6 FWPM_LAYER_DATAGRAM_DATA_V4_DISCARD FWPM_LAYER_DATAGRAM_DATA_V6_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V4 FWPM_LAYER_INBOUND_ICMP_ERROR_V6 FWPM_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD

	FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD This flag is applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_ALE_CONNECT_REDIRECT_V4 FWPM_LAYER_ALE_CONNECT_REDIRECT_V6 FWPM_LAYER_ALE_BIND_REDIRECT_V4 FWPM_LAYER_ALE_BIND_REDIRECT_V6
FWP_CONDITION_FLAG_IS_FRAGMENT 0x00000020	Indicates that the **NET_BUFFER_LIST** structure passed to a callout driver is an IP packet fragment. This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V6 FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD
FWP_CONDITION_FLAG_IS_FRAGMENT_GROUP 0x00000040	Indicates that the **NET_BUFFER_LIST** structure passed to a callout driver describes a linked list of packet fragments. This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V6 FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD
FWP_CONDITION_FLAG_IS_IPSEC_NATT_RECLASSIFY 0x00000080	This flag is set when an NAT Traversal (UDP port 4500) packet is indicated. Once the decapsulation occurs, the flag is set for the reclassify using the information from the encapsulated packet. This flag is applicable at the following filtering layers: FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V4 FWPM_LAYER_OUTBOUND_TRANSPORT_V6 FWPM_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD
FWP_CONDITION_FLAG_REQUIRES_ALE_CLASSIFY 0x00000100	Indicates that the packet has not yet reached the ALE receive/accept layer (FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 or FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6), where its connection state will be tracked. This flag is applicable at the following filtering layers:

	FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD
FWP_CONDITION_FLAG_IS_IMPLICIT_BIND 0x00000200	Indicates that the socket was not explicitly bound. If the sender calls send without first calling bind, Windows Sockets performs an implicit bind. **Note** This flag is supported only in Windows Server 2008 and Windows Vista. It is deprecated in later Windows versions. This flag is applicable at the following filtering layers: FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V4_DISCARD FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD
FWP_CONDITION_FLAG_IS_REASSEMBLED 0x00000400	Indicates that the packet has been reassembled from a group of fragments. This flag is applicable at the following filtering layers in Windows Server 2008, Windows Vista with Service Pack 1 (SP1), and later versions of Windows: FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V6 FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD
FWP_CONDITION_FLAG_IS_NAME_APP_SPECIFIED 0x00004000	Indicates that the name of the peer machine that the application is expecting to connect to has been obtained by calling a function such as **WSASetSocketPeerTargetName** and not by using the caching heuristics. This flag is applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD
FWP_CONDITION_FLAG_IS_PROMISCUOUS 0x00008000	Reserved for future use.
FWP_CONDITION_FLAG_IS_AUTH_FW 0x00010000	Indicates that a packet matches authenticated firewall policies. Only connections matching the "Allow the connection if it is secure" firewall rule option will have this flag set. For more information, see How to Enable Authenticated Firewall Bypass.

	This flag is also applicable at the following filtering layers in Windows Server 2008, Windows Vista with SP1, and later versions of Windows: FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD This flag is also applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD
FWP_CONDITION_FLAG_IS_RECLASSIFY 0x00020000	This flag is set when the IPV6_PROTECTION_LEVEL socket option is set on a previously authorized socket. This flag is applicable at the following filtering layers: FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6 FWPM_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD FWPM_LAYER_ALE_AUTH_LISTEN_V6 FWPM_LAYER_ALE_AUTH_LISTEN_V6_DISCARD
FWP_CONDITION_FLAG_IS_OUTBOUND_PASS_THRU 0x00040000	Indicates that the packet is weak-host sent, which means that it isn't leaving this network interface and therefore must be forwarded to another interface. This flag is applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_IPFORWARD_V4 FWPM_LAYER_IPFORWARD_V6 FWPM_LAYER_IPFORWARD_V4_DISCARD FWPM_LAYER_IPFORWARD_V6_DISCARD
FWP_CONDITION_FLAG_IS_INBOUND_PASS_THRU 0x00080000	Indicates that the packet is weak-host received, which means that it isn't destined for the receiving network interface and therefore must be forwarded to another interface. This flag is applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_IPFORWARD_V4 FWPM_LAYER_IPFORWARD_V6 FWPM_LAYER_IPFORWARD_V4_DISCARD FWPM_LAYER_IPFORWARD_V6_DISCARD
FWP_CONDITION_FLAG_IS_CONNECTION_REDIRECTED 0x00100000	Indicates that the connection was redirected by an ALE_CONNECT_REDIRECT callout function.

	This flag is applicable at the following filtering layers in Windows Server 2008 R2, Windows 7, and later versions of Windows: FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD
FWP_CONDITION_FLAG_IS_PROXY_CONNECTION 0x00200000	Indicates that the connection has been proxied, and therefore previous redirect records exist. This flag is applicable at the following filtering layers in Windows Server 2012, Windows 8, and later versions of Windows: FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6 FWPM_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPM_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD FWPM_LAYER_ALE_CONNECT_REDIRECT_V4 FWPM_LAYER_ALE_CONNECT_REDIRECT_V6
FWP_CONDITION_FLAG_IS_APPCONTAINER_LOOPBACK 0x00400000	Indicates that the traffic is going to and from an AppContainer that is using loopback. This flag is applicable at the following filtering layers in Windows Server 2012, Windows 8, and later versions of Windows: FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD
FWP_CONDITION_FLAG_IS_NON_APPCONTAINER_LOOPBACK 0x00800000	Indicates that the traffic is going to and from a standard app (not an AppContainer) that is using loopback. This flag is applicable at the following filtering layers in Windows Server 2012, Windows 8, and later versions of Windows: FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD
FWP_CONDITION_FLAG_IS_RESERVED	Reserved for future use.

0x01000000	
FWP_CONDITION_FLAG_IS_HONORING_POLICY_AUTHORIZE 0x02000000	Indicates that the current classification is being performed to honor the intention of a redirected Universal Windows app to connect to a specified host. Such a classification will contain the same classifiable field values as if the app were never redirected. The flag also indicates that a future classification will be invoked to match the effective redirected destination. If the app is redirected to a proxy service for inspection, it also means a future classification will be invoked on the proxy connection. Callouts should use FWPS_FIELD_ALE_AUTH_CONNECT_V4_ALE_ORIGINAL_APP_ID to find the appid of the (original) redirected connection. This flag is applicable at the following filtering layers in Windows Server 2012, Windows 8, and later versions of Windows: FWPM_LAYER_ALE_AUTH_CONNECT_V4 FWPM_LAYER_ALE_AUTH_CONNECT_V6 FWPM_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPM_LAYER_ALE_AUTH_CONNECT_V6_DISCARD

Filtering condition L2 flags

Article • 12/15/2021

The filtering condition L2 flags are each represented by a bit field. These flags are defined as follows:

Filtering condition flag	Description
FWP_CONDITION_L2_IS_NATIVE_ETHERNET 0x00000001	Tests if the data passed to a callout driver describes a native Ethernet packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE Tests if the data passed to a callout driver describes a WIFI packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_WIFI 0x00000002	Tests if the data passed to a callout driver describes a native Wi-Fi packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_MOBILE_BROADBAND 0x00000004	Tests if the data passed to a callout driver describes a mobile broadband packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET

	FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_WIFI_DIRECT_DATA 0x00000008	Tests if the data passed to a callout driver describes a WIFI direct data packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_VM2VM 0x00000010	Tests if the data passed to a callout driver describes a native virtual machine to virtual machine packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_MALFORMED_PACKET 0x00000020	Tests if the data passed to a callout driver describes a malformed Ethernet packet. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IS_IP_FRAGMENT_GROUP 0x00000040	Tests if the data passed to a callout driver describes a part of an IP fragment group. This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE
FWP_CONDITION_L2_IF_CONNECTOR_PRESENT 0x00000080	Tests if a network interface connector is present on the underlying network adapter. This flag should be set for a physical adapter.

	This flag is applicable at the following filtering layers in Windows 8, Windows Server 2012, and later versions of Windows: FWPM_LAYER_INBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_OUTBOUND_MAC_FRAME_ETHERNET FWPM_LAYER_INBOUND_MAC_FRAME_NATIVE FWPM_LAYER_OUTBOUND_MAC_FRAME_NATIVE

Filtering condition data types

Article • 12/15/2021

The data type for the condition value for each filtering condition is specified as an FWP_DATA_TYPE value as follows.

Filtering condition identifier	Condition value data type
FWPM_CONDITION_IP_LOCAL_ADDRESS	For an IPv4 address: FWP_V4_ADDR_MASK or FWP_UINT32 For an IPv6 address: FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_IP_REMOTE_ADDRESS	For an IPv4 address: FWP_V4_ADDR_MASK or FWP_UINT32 For an IPv6 address: FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_IP_SOURCE_ADDRESS	For an IPv4 address: FWP_V4_ADDR_MASK or FWP_UINT32 For an IPv6 address: FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_IP_DESTINATION_ADDRESS	For an IPv4 address: FWP_V4_ADDR_MASK or FWP_UINT32 For an IPv6 address: FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_IP_DESTINATION_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_IP_LOCAL_INTERFACE	FWP_UINT64
FWPM_CONDITION_IP_FORWARD_INTERFACE	FWP_UINT64
FWPM_CONDITION_IP_PROTOCOL	FWP_UINT8

FWPM_CONDITION_IP_LOCAL_PORT	FWP_UINT16
FWPM_CONDITION_IP_REMOTE_PORT	FWP_UINT16
FWPM_CONDITION_ICMP_TYPE	FWP_UINT16
FWPM_CONDITION_ICMP_CODE	FWP_UINT16
FWPM_CONDITION_EMBEDDED_LOCAL_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_EMBEDDED_REMOTE_ADDRESS	For an IPv4 address: FWP_V4_ADDR_MASK or FWP_UINT32 For an IPv6 address: FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_EMBEDDED_PROTOCOL	FWP_UINT8
FWPM_CONDITION_EMBEDDED_LOCAL_PORT	FWP_UINT16
FWPM_CONDITION_EMBEDDED_REMOTE_PORT	FWP_UINT16
FWPM_CONDITION_FLAGS	FWP_UINT32
FWPM_CONDITION_DIRECTION	FWP_UINT32
FWPM_CONDITION_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_SUB_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_SOURCE_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_SOURCE_SUB_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_DESTINATION_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_DESTINATION_SUB_INTERFACE_INDEX	FWP_UINT32
FWPM_CONDITION_ALE_APP_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_ALE_USER_ID	FWP_SECURITY_DESCRIPTOR_TYPE
FWPM_CONDITION_ALE_REMOTE_USER_ID	FWP_SECURITY_DESCRIPTOR_TYPE
FWPM_CONDITION_ALE_REMOTE_MACHINE_ID	FWP_SECURITY_DESCRIPTOR_TYPE
FWPM_CONDITION_ALE_PROMISCUOUS_MODE	FWP_UNIT32
FWPM_CONDITION_ALE_SIO_FIREWALL_SYSTEM_PORT	FWP_UINT32
FWPM_CONDITION_ALE_NAP_CONTEXT	FWP_UINT32

FWPM_CONDITION_REMOTE_USER_TOKEN	FWP_SECURITY_DESCRIPTOR_TYPE
FWPM_CONDITION_RPC_IF_UUID	FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_RPC_IF_VERSION	FWP_UINT16
FWPM_CONDITION_RPC_IF_FLAG	FWP_UINT32
FWPM_CONDITION_DCOM_APP_ID	FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_IMAGE_NAME	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_RPC_PROTOCOL	FWP_UINT8
FWPM_CONDITION_RPC_AUTH_TYPE	FWP_UINT8
FWPM_CONDITION_RPC_AUTH_LEVEL	FWP_UINT8
FWPM_CONDITION_SEC_ENCRYPT_ALGORITHM	FWP_UINT32
FWPM_CONDITION_SEC_KEY_SIZE	FWP_UINT32
FWPM_CONDITION_IP_LOCAL_ADDRESS_V4	FWP_V4_ADDR_MASK or FWP_UINT32
FWPM_CONDITION_IP_LOCAL_ADDRESS_V6	FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_PIPE	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_IP_REMOTE_ADDRESS_V4	FWP_V4_ADDR_MASK or FWP_UINT32
FWPM_CONDITION_IP_REMOTE_ADDRESS_V6	FWP_V6_ADDR_MASK or FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_PROCESS_WITH_RPC_IF_UUID	FWP_BYTE_ARRAY16_TYPE
FWPM_CONDITION_RPC_EP_VALUE	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_RPC_EP_FLAGS	FWP_UINT32
FWPM_CONDITION_CLIENT_TOKEN	FWP_SECURITY_DESCRIPTOR_TYPE
FWPM_CONDITION_RPC_SERVER_NAME	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_RPC_SERVER_PORT	FWP_UINT16
FWPM_CONDITION_RPC_PROXY_AUTH_TYPE	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_CLIENT_CERT_KEY_LENGTH	FWP_UINT32
FWPM_CONDITION_CLIENT_CERT_OID	FWP_BYTE_BLOB_TYPE

FWPM_CONDITION_INTERFACE_MAC_ADDRESS	FWP_BYTE_ARRAY6_TYPE
FWPM_CONDITION_LOCAL_MAC_ADDRESS	FWP_BYTE_ARRAY6_TYPE
FWPM_CONDITION_REMOTE_MAC_ADDRESS	FWP_BYTE_ARRAY6_TYPE
FWPM_CONDITION_ETHER_TYPE	FWP_UINT16
FWPM_CONDITION_VLAN_ID	FWP_UINT16
FWPM_CONDITION_NDIS_PORT	FWP_UINT16
FWPM_CONDITION_NDIS_MEDIA_TYPE	FWP_UINT16
FWPM_CONDITION_NDIS_PHYSICAL_MEDIA_TYPE	FWP_UINT16

FWPM_CONDITION_LOCAL_MAC_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_REMOTE_MAC_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_INTERFACE	FWP_UINT64
FWPM_CONDITION_PACKAGE_ID	FWP_SID
FWPM_CONDITION_MAC_SOURCE_ADDRESS	FWP_BYTE_ARRAY6_TYPE
FWPM_CONDITION_MAC_DESTINATION_ADDRESS	FWP_BYTE_ARRAY6_TYPE
FWPM_CONDITION_MAC_SOURCE_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_MAC_DESTINATION_ADDRESS_TYPE	FWP_UINT8
FWPM_CONDITION_IP_SOURCE_PORT	FWP_UINT16
FWPM_CONDITION_IP_DESTINATION_PORT	FWP_UINT16
FWPM_CONDITION_VSWITCH_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_VSWITCH_NETWORK_TYPE	FWP_UINT8
FWPM_CONDITION_VSWITCH_SOURCE_INTERFACE_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_VSWITCH_DESTINATION_INTERFACE_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_VSWITCH_SOURCE_INTERFACE_TYPE	FWP_UINT8
FWPM_CONDITION_VSWITCH_DESTINATION_INTERFACE_TYPE	FWP_UINT8
FWPM_CONDITION_VSWITCH_SOURCE_VM_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_VSWITCH_DESTINATION_VM_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_VSWITCH_TENANT_NETWORK_ID	FWP_UINT16

FWPM_CONDITION_ALE_PACKAGE_ID	FWP_SID
FWPM_CONDITION_ALE_ORIGINAL_APP_ID	FWP_BYTE_BLOB_TYPE
FWPM_CONDITION_QM_MODE	FWP_UINT32

Filtering conditions available at each filtering layer

Article • 12/15/2021

The filtering conditions that are available at each filtering layer are as follows.

> **Note**
>
> The V4 and V6 suffixes at the end of the layer identifiers indicate whether the layer is located in the IPv4 network stack or in the IPv6 network stack.

Management filtering layer identifier	Available filtering conditions
FWPM_LAYER_INBOUND_IPPACKET_V4 FWPM_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_INBOUND_IPPACKET_V6 FWPM_LAYER_INBOUND_IPPACKET_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_FLAGS FWPM_CONDITION_INTERFACE_INDEX FWPM_CONDITION_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX FWPM_CONDITION_TUNNEL_TYPE
FWPM_LAYER_OUTBOUND_IPPACKET_V4 FWPM_LAYER_OUTBOUND_IPPACKET_V4_DISCARD FWPM_LAYER_OUTBOUND_IPPACKET_V6 FWPM_LAYER_OUTBOUND_IPPACKET_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_FLAGS FWPM_CONDITION_INTERFACE_INDEX FWPM_CONDITION_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX FWPM_CONDITION_TUNNEL_TYPE
FWPM_LAYER_IPFORWARD_V4 FWPM_LAYER_IPFORWARD_V4_DISCARD FWPM_LAYER_IPFORWARD_V6 FWPM_LAYER_IPFORWARD_V6_DISCARD	FWPM_CONDITION_IP_SOURCE_ADDRESS FWPM_CONDITION_IP_DESTINATION_ADDRESS FWPM_CONDITION_IP_DESTINATION_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE

	FWPM_CONDITION_IP_FORWARD_INTERFACE FWPM_CONDITION_FLAGS FWPM_CONDITION_SOURCE_INTERFACE_INDEX FWPM_CONDITION_SOURCE_SUB_INTERFACE_INDEX FWPM_CONDITION_DESTINATION_INTERFACE_INDEX FWPM_CONDITION_DESTINATION_SUB_INTERFACE_INDEX
FWPM_LAYER_INBOUND_TRANSPORT_V4 FWPM_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_INBOUND_TRANSPORT_V6 FWPM_LAYER_INBOUND_TRANSPORT_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_IP_PROTOCOL FWPM_CONDITION_IP_LOCAL_PORT FWPM_CONDITION_IP_REMOTE_PORT FWPM_CONDITION_FLAGS FWPM_CONDITION_INTERFACE_INDEX FWPM_CONDITION_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX FWPM_CONDITION_TUNNEL_TYPE
FWPM_LAYER_OUTBOUND_TRANSPORT_V4 FWPM_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPM_LAYER_OUTBOUND_TRANSPORT_V6 FWPM_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_DESTINATION_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_IP_PROTOCOL FWPM_CONDITION_IP_LOCAL_PORT FWPM_CONDITION_IP_REMOTE_PORT FWPM_CONDITION_FLAGS FWPM_CONDITION_INTERFACE_INDEX FWPM_CONDITION_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX FWPM_CONDITION_TUNNEL_TYPE
FWPM_LAYER_STREAM_V4 FWPM_LAYER_STREAM_V4_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS

FWPM_LAYER_STREAM_V6 FWPM_LAYER_STREAM_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_PORT FWPM_CONDITION_IP_REMOTE_PORT FWPM_CONDITION_FLAGS FWPM_CONDITION_DIRECTION
FWPM_LAYER_DATAGRAM_DATA_V4 FWPM_LAYER_DATAGRAM_DATA_V4_DISCARD FWPM_LAYER_DATAGRAM_DATA_V6 FWPM_LAYER_DATAGRAM_DATA_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_ADDRESS_TYPE FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_IP_PROTOCOL FWPM_CONDITION_IP_LOCAL_PORT FWPM_CONDITION_IP_REMOTE_PORT FWPM_CONDITION_FLAGS FWPM_CONDITION_DIRECTION FWPM_CONDITION_INTERFACE_INDEX FWPM_CONDITION_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX FWPM_CONDITION_TUNNEL_TYPE
FWPM_LAYER_INBOUND_ICMP_ERROR_V4 FWPM_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPM_LAYER_INBOUND_ICMP_ERROR_V6 FWPM_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD	FWPM_CONDITION_IP_LOCAL_ADDRESS FWPM_CONDITION_IP_REMOTE_ADDRESS FWPM_CONDITION_IP_LOCAL_INTERFACE FWPM_CONDITION_IP_ARRIVAL_INTERFACE FWPM_CONDITION_FLAGS FWPM_CONDITION_ICMP_TYPE FWPM_CONDITION_ICMP_CODE FWPM_CONDITION_EMBEDDED_LOCAL_ADDRESS_TYPE FWPM_CONDITION_EMBEDDED_REMOTE_ADDRESS FWPM_CONDITION_EMBEDDED_PROTOCOL FWPM_CONDITION_EMBEDDED_LOCAL_PORT FWPM_CONDITION_EMBEDDED_REMOTE_PORT FWPM_CONDITION_ARRIVAL_INTERFACE_INDEX FWPM_CONDITION_ARRIVAL_INTERFACE_TYPE FWPM_CONDITION_SUB_INTERFACE_INDEX

	Note In Windows Vista, this flag was called FWPM_CONDITION_ARRIVAL_SUB_INTERFACE_INDEX. In Windows Vista with Service Pack 1 (SP1) and later, both names are valid. FWPM_CONDITION_ARRIVAL_TUNNEL_TYPE FWPM_CONDITION_INTERFACE_INDEX **Note** In Windows Vista, this flag was called FWPM_CONDITION_LOCAL_INTERFACE_INDEX. In Windows Vista with SP1 and later, both names are valid. FWPM_CONDITION_INTERFACE_TYPE **Note** In Windows Vista, this flag was called FWPM_CONDITION_LOCAL_INTERFACE_TYPE. In Windows Vista with SP1 and later, both names are valid. FWPM_CONDITION_TUNNEL_TYPE **Note** In Windows Vista, this flag was called FWPM_CONDITION_LOCAL_TUNNEL_TYPE. In Windows Vista with SP1 and later, both names are valid.

Metadata field identifiers

Article • 12/15/2021

The metadata field identifiers are each represented by a bit-field. These identifiers are defined as follows:

Metadata field identifier	Description
FWPS_METADATA_FIELD_ALE_CLASSIFY_REQUIRED	The inbound packet will also be indicated to the FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V4 and FWPM_LAYER_ALE_AUTH_RECV_ACCEPT_V6 filtering layers. **Note:** Supported in Windows Server 2008, Windows Vista with Service Pack 1 (SP1), and later.
FWPS_METADATA_FIELD_COMPARTMENT_ID	The identifier of the routing compartment in which the packet was received or is being sent.
FWPS_METADATA_FIELD_COMPLETION_HANDLE	The completion handle used to pend the current filtering operation.
FWPS_METADATA_FIELD_DESTINATION_INTERFACE_INDEX	The index of the network interface where the outgoing packet is to be sent.
FWPS_METADATA_FIELD_DESTINATION_PREFIX	The destination IPV4 or IPV6 address and subnet mask for the outgoing packets. **Note:** Supported starting with Windows 7.
FWPS_METADATA_FIELD_DISCARD_REASON	The reason that the data was discarded.
FWPS_METADATA_FIELD_ETHER_FRAME_LENGTH	This metadata field identifier is not currently supported.
FWPS_METADATA_FIELD_FLOW_HANDLE	The handle for the data flow.
FWPS_METADATA_FIELD_FORWARD_LAYER_INBOUND_PASS_THRU	The packet that traverses the FWPM_LAYER_IPFORWARD_V4 or FWPM_LAYER_IPFORWARD_V6 forward layer is locally destined (its destination matches an address that is assigned to an interface of the host). **Note:** Supported in Windows Server 2008, Windows Vista with SP1, and later.

Metadata field identifier	Description
FWPS_METADATA_FIELD_FORWARD_LAYER_OUTBOUND_PASS_THRU	The packet that traverses the FWPM_LAYER_IPFORWARD_V4 or FWPM_LAYER_IPFORWARD_V6 forward layer originated locally. **Note:** Supported in Windows Server 2008, Windows Vista with SP1, and later.
FWPS_METADATA_FIELD_FRAGMENT_DATA	The fragment data for a received packet fragment.
FWPS_METADATA_FIELD_ICMP_ID_AND_SEQUENCE	The Identifier and Sequence Number fields of an ICMP Echo Request or Echo Reply packet. **Note:** Supported starting with Windows 7.
FWPS_METADATA_FIELD_IP_HEADER_SIZE	The size of the IP header.
FWPS_METADATA_FIELD_LOCAL_REDIRECT_TARGET_PID	The Process ID that a connection was redirected to. **Note:** Supported starting with Windows 7.
FWPS_METADATA_FIELD_ORIGINAL_DESTINATION	A SOCKADDR_STORAGE structure that indicate the packet's original destination. **Note:** Supported starting with Windows 7.
FWPS_METADATA_FIELD_PACKET_DIRECTION	The direction of network traffic (inbound or outbound).
FWPS_METADATA_FIELD_PACKET_SYSTEM_CRITICAL	Reserved for system use. Do not use. **Note:** Supported in Windows Server 2008, Windows Vista with SP1, and later.
FWPS_METADATA_FIELD_PARENT_ENDPOINT_HANDLE	The handle of the endpoint's parent socket. **Note:** Supported starting with Windows 7.
FWPS_METADATA_FIELD_PATH_MTU	The path maximum transmission unit (path MTU) for an outgoing packet.
FWPS_METADATA_FIELD_PROCESS_ID	The process ID for the process that owns the endpoint.
FWPS_METADATA_FIELD_PROCESS_PATH	The full path to the process that owns the endpoint.
FWPS_METADATA_FIELD_REDIRECT_RECORD_HANDLE	The redirect records handle indicated to ALE_CONNECT_REDIRECT callout by the classify metadata. **Note:** Supported starting with Windows 8.
FWPS_METADATA_FIELD_REMOTE_SCOPE_ID	The remote scope identifier to be used in outbound transport layer injection.
FWPS_METADATA_FIELD_RESERVED	Reserved for system use. Do not use.

Metadata field identifier	Description
FWPS_METADATA_FIELD_SOURCE_INTERFACE_INDEX	The index of the network interface where the incoming packet was received.
FWPS_METADATA_FIELD_SUB_PROCESS_TAG	Reserved for system use.
FWPS_METADATA_FIELD_SYSTEM_FLAGS	System flags that are used internally by the filter engine.
FWPS_METADATA_FIELD_TOKEN	The token used to validate the permissions for the user.
FWPS_METADATA_FIELD_TRANSPORT_CONTROL_DATA	An optional socket control data object.
FWPS_METADATA_FIELD_TRANSPORT_ENDPOINT_HANDLE	The handle for the end of the packet to be injected into the outbound transport layer.
FWPS_METADATA_FIELD_TRANSPORT_HEADER_INCLUDE_HEADER	The IP header if the packet is sent from a raw socket. **Note:** Supported in Windows Server 2008, Windows Vista with SP1, and later.
FWPS_METADATA_FIELD_TRANSPORT_HEADER_SIZE	The size of the transport header.

Metadata field L2 identifiers

Article • 12/15/2021

Windows 8 and Windows Server 2012 introduce metadata field L2 identifiers.

The metadata field L2 identifiers are each represented by a bit field. These identifiers are defined as follows:

Metadata field identifier	Description
FWPS_L2_METADATA_FIELD_ETHERNET_MAC_HEADER_SIZE	The size, in bytes, of the MAC header.
FWPS_L2_METADATA_FIELD_VSWITCH_DESTINATION_PORT_ID	The identifier for the destination port on the virtual switch.
FWPS_L2_METADATA_FIELD_VSWITCH_PACKET_CONTEXT	A **HANDLE** to the virtual switch packet context.
FWPS_L2_METADATA_FIELD_VSWITCH_SOURCE_NIC_INDEX	The index for the source NIC on the virtual switch.
FWPS_L2_METADATA_FIELD_VSWITCH_SOURCE_PORT_ID	The identifier for the source port on the virtual switch.
FWPS_L2_METADATA_FIELD_WIFI_OPERATION_MODE	The current Native 802.11 operation mode.

Metadata fields at each filtering layer

Article • 12/15/2021

The following table lists the possible metadata fields that are available by layer. Some fields are available only under specific circumstances. For example, the metadata field FWPS_METADATA_FIELD_FRAGMENT_DATA is available for inbound IP packet layers only if the packet is fragmented. Layers that are not listed in the table do not have any available metadata fields.

Run-time filtering layer identifier	Metadata fields
FWPS_LAYER_INBOUND_IPPACKET_V4 FWPS_LAYER_INBOUND_IPPACKET_V6	FWPS_METADATA_FIELD_IP_HEADER_SIZE FWPS_METADATA_FIELD_COMPARTMENT_ID FWPS_METADATA_FIELD_FRAGMENT_DATA

Data field identifiers

Article • 12/15/2021

The run-time filtering layers are associated with data field identifiers. These identifiers represent a set of constant values that are declared as FWPS_FIELDS_XXX enumerations in Fwpsk.h.

The following table lists the run-time filtering layers and the associated data field enumerations.

Run-time filtering layer	Data field enumeration
FWPS_LAYER_INBOUND_IPPACKET_V4 FWPS_LAYER_INBOUND_IPPACKET_V4_DISCARD	FWPS_FIELDS_INBOUND_IPPACKET_V4
FWPS_LAYER_INBOUND_IPPACKET_V6 FWPS_LAYER_INBOUND_IPPACKET_V6_DISCARD	FWPS_FIELDS_INBOUND_IPPACKET_V6
FWPS_LAYER_OUTBOUND_IPPACKET_V4 FWPS_LAYER_OUTBOUND_IPPACKET_V4_DISCARD	FWPS_FIELDS_OUTBOUND_IPPACKET_V4
FWPS_LAYER_OUTBOUND_IPPACKET_V6 FWPS_LAYER_OUTBOUND_IPPACKET_V6_DISCARD	FWPS_FIELDS_OUTBOUND_IPPACKET_V6
FWPS_LAYER_IPFORWARD_V4 FWPS_LAYER_IPFORWARD_V4_DISCARD	FWPS_FIELDS_IPFORWARD_V4
FWPS_LAYER_IPFORWARD_V6 FWPS_LAYER_IPFORWARD_V6_DISCARD	FWPS_FIELDS_IPFORWARD_V6
FWPS_LAYER_INBOUND_TRANSPORT_V4 FWPS_LAYER_INBOUND_TRANSPORT_V4_DISCARD	FWPS_FIELDS_INBOUND_TRANSPORT_V4
FWPS_LAYER_INBOUND_TRANSPORT_V6 FWPS_LAYER_INBOUND_TRANSPORT_V6_DISCARD	FWPS_FIELDS_INBOUND_TRANSPORT_V6

Data offset positions

Article • 12/15/2021

When the filter engine calls a callout driver's classifyFn callout function, it passes a pointer to a structure in the *layerData* parameter. For the layers that filter packet data, the pointer references a NET_BUFFER_LIST structure. Depending on the filtering layer at which the *classifyFn* callout function is called, the filter engine passes a pointer in the layerData* parameter to one of the following structures:

- For the stream layer, the *layerData* parameter contains a pointer to an FWPS_STREAM_CALLOUT_IO_PACKET0 structure. The streamData member of this structure contains a pointer to an FWPS_STREAM_DATA0 structure.

  The **netBufferListChain** member of the FWPS_STREAM_DATA0 structure contains a pointer to a NET_BUFFER_LIST structure.

- For all the other layers, the *layerData* parameter contains a pointer to a NET_BUFFER_LIST structure.

> ⓘ Note
>
> The *layerData* parameter might be NULL, depending on the layer being filtered and the conditions under which the driver's **classifyFn** callout function is called.

The NET_BUFFER_LIST structure contains a linked list of NET_BUFFER structures. Within the NET_BUFFER_DATA structure of each **NET_BUFFER** structure, the **DataOffset** member points to a specific position in the packet data. The position that the **DataOffset** member points to depends on the filtering layer at which the filter engine calls the callout driver's *classifyFn* callout function.

For each filtering layer, the position in the packet data as specified by the **DataOffset** member is defined as follows:

Run-time filtering layer identifier (starting with Windows Vista)	Position in the packet data
FWPS_LAYER_INBOUND_IPPACKET_V4 FWPS_LAYER_INBOUND_IPPACKET_V6	The beginning of the transport header.
FWPS_LAYER_INBOUND_IPPACKET_V4_DISCARD FWPS_LAYER_INBOUND_IPPACKET_V6_DISCARD	The offset where the TCP/IP stack stopped processing.

FWPS_LAYER_OUTBOUND_IPPACKET_V4 FWPS_LAYER_OUTBOUND_IPPACKET_V6	The beginning of the IP header.
FWPS_LAYER_OUTBOUND_IPPACKET_V4_DISCARD FWPS_LAYER_OUTBOUND_IPPACKET_V6_DISCARD	The offset where the TCP/IP stack stopped processing.
FWPS_LAYER_IPFORWARD_V4 FWPS_LAYER_IPFORWARD_V6	The beginning of the IP header.
FWPS_LAYER_IPFORWARD_V4_DISCARD FWPS_LAYER_IPFORWARD_V6_DISCARD	The beginning of the IP header.
FWPS_LAYER_INBOUND_TRANSPORT_V4 FWPS_LAYER_INBOUND_TRANSPORT_V6	The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header.
FWPS_LAYER_INBOUND_TRANSPORT_V4_DISCARD FWPS_LAYER_INBOUND_TRANSPORT_V6_DISCARD	The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header.
FWPS_LAYER_OUTBOUND_TRANSPORT_V4 FWPS_LAYER_OUTBOUND_TRANSPORT_V6	The beginning of the transport header.
FWPS_LAYER_OUTBOUND_TRANSPORT_V4_DISCARD FWPS_LAYER_OUTBOUND_TRANSPORT_V6_DISCARD	The beginning of the transport header.
FWPS_LAYER_STREAM_V4 FWPS_LAYER_STREAM_V6	The beginning of the data. **Note** The position in the packet data contains no IP, IPv6, and transport headers.

FWPS_LAYER_STREAM_V4_DISCARD FWPS_LAYER_STREAM_V6_DISCARD	The beginning of the data. **Note** The position in the packet data contains no IP, IPv6, or transport headers.
FWPS_LAYER_DATAGRAM_DATA_V4 FWPS_LAYER_DATAGRAM_DATA_V6	For inbound datagrams: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound datagrams: The beginning of the transport header.
FWPS_LAYER_DATAGRAM_DATA_V4_DISCARD FWPS_LAYER_DATAGRAM_DATA_V6_DISCARD	For inbound datagrams: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound datagrams: The beginning of the transport header.
FWPS_LAYER_INBOUND_ICMP_ERROR_V4 FWPS_LAYER_INBOUND_ICMP_ERROR_V6	The beginning of the inner IP header.
FWPS_LAYER_INBOUND_ICMP_ERROR_V4_DISCARD FWPS_LAYER_INBOUND_ICMP_ERROR_V6_DISCARD	The beginning of the inner IP header.
FWPS_LAYER_OUTBOUND_ICMP_ERROR_V4 FWPS_LAYER_OUTBOUND_ICMP_ERROR_V6	The beginning of the ICMP header.

FWPS_LAYER_OUTBOUND_ICMP_ERROR_V4_DISCARD FWPS_LAYER_OUTBOUND_ICMP_ERROR_V6_DISCARD	The beginning of the ICMP header.
FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V4 FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V6	Not applicable.
FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V4_DISCARD FWPS_LAYER_ALE_RESOURCE_ASSIGNMENT_V6_DISCARD	Not applicable.
FWPS_LAYER_ALE_AUTH_LISTEN_V4 FWPS_LAYER_ALE_AUTH_LISTEN_V6	Not applicable.
FWPS_LAYER_ALE_AUTH_LISTEN_V4_DISCARD FWPS_LAYER_ALE_AUTH_LISTEN_V6_DISCARD	Not applicable.
FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4 FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6	For inbound packet direction: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound packet direction: The beginning of the transport header.
FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V4_DISCARD FWPS_LAYER_ALE_AUTH_RECV_ACCEPT_V6_DISCARD	For inbound packet direction: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound packet direction: The beginning of the transport header.
FWPS_LAYER_ALE_AUTH_CONNECT_V4	For non-TCP traffic: The beginning of the transport header.

FWPS_LAYER_ALE_AUTH_CONNECT_V6	For TCP traffic: Not applicable.
FWPS_LAYER_ALE_AUTH_CONNECT_V4_DISCARD FWPS_LAYER_ALE_AUTH_CONNECT_V6_DISCARD	For non-TCP traffic: The beginning of the transport header. For TCP traffic: Not applicable.
FWPS_LAYER_ALE_FLOW_ESTABLISHED_V4 FWPS_LAYER_ALE_FLOW_ESTABLISHED_V6	For inbound packet direction: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound packet direction: The beginning of the transport header.
FWPS_LAYER_ALE_FLOW_ESTABLISHED_V4_DISCARD FWPS_LAYER_ALE_FLOW_ESTABLISHED_V6_DISCARD	For inbound packet direction: The beginning of the data. **Note** For inbound packets received on the ICMP socket of the TCP/IP stack, the offset is the beginning of the ICMP header. For outbound packet direction: The beginning of the transport header.
FWPS_LAYER_IPSEC_KM_DEMUX_V4 FWPS_LAYER_IPSEC_KM_DEMUX_V6	Not applicable.
FWPS_LAYER_IPSEC_V4 FWPS_LAYER_IPSEC_V6	Not applicable.
FWPS_LAYER_IKEEXT_V4 FWPS_LAYER_IKEEXT_V6	Not applicable.
FWPS_LAYER_RPC_UM	Not applicable.
FWPS_LAYER_RPC_EPMAP	Not applicable.

FWPS_LAYER_RPC_EP_ADD	Not applicable.
FWPS_LAYER_RPC_PROXY_CONN	Not applicable.
FWPS_LAYER_RPC_PROXY_IF	Not applicable.

Run-time filtering layer identifier (starting with Windows 7)	Position in the packet data
FWPS_LAYER_NAME_RESOLUTION_CACHE_V4 FWPS_LAYER_NAME_RESOLUTION_CACHE_V6	Not applicable.
FWPS_LAYER_ALE_RESOURCE_RELEASE_V4 FWPS_LAYER_ALE_RESOURCE_RELEASE_V6	Not applicable.
FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V4 FWPS_LAYER_ALE_ENDPOINT_CLOSURE_V6	Not applicable.
FWPS_LAYER_ALE_CONNECT_REDIRECT_V4 FWPS_LAYER_ALE_CONNECT_REDIRECT_V6	Not applicable. **Note** For these filtering layers, the *layerData* parameter contains a pointer to an **FWPS_CONNECT_REQUEST0** structure. This structure does not reference a **NET_BUFFER_LIST** structure that describes packet data.
FWPS_LAYER_ALE_BIND_REDIRECT_V4 FWPS_LAYER_ALE_BIND_REDIRECT_V6	Not applicable. **Note** For these filtering layers, the *layerData* parameter contains a pointer to an **FWPS_BIND_REQUEST0** structure. This structure does not reference a **NET_BUFFER_LIST** structure that describes packet data.

FWPS_LAYER_STREAM_PACKET_V4 FWPS_LAYER_STREAM_PACKET_V6	For inbound packet direction: The beginning of the data. For outbound packet direction: The beginning of the transport header.
FWPS_LAYER_KM_AUTHORIZATION	Not applicable.
Run-time filtering layer identifier (starting with Windows 8)	**Position in the packet data**
FWPS_LAYER_INBOUND_MAC_FRAME_ETHERNET	The beginning of the IP header.
FWPS_LAYER_OUTBOUND_MAC_FRAME_ETHERNET	The beginning of the MAC header.
FWPS_LAYER_INBOUND_MAC_FRAME_NATIVE	The beginning of the MAC header.
FWPS_LAYER_OUTBOUND_MAC_FRAME_NATIVE	The beginning of the MAC header.
FWPS_LAYER_INGRESS_VSWITCH_ETHERNET	The beginning of the ethernet header.
FWPS_LAYER_EGRESS_VSWITCH_ETHERNET	The beginning of the ethernet header.
FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V4	The beginning of the IP header.
FWPS_LAYER_INGRESS_VSWITCH_TRANSPORT_V6	The beginning of the IP header.
FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V4	The beginning of the IP header.
FWPS_LAYER_EGRESS_VSWITCH_TRANSPORT_V6	The beginning of the IP header.

General discard reasons

Article • 12/15/2021

The identifiers for the possible reasons that the data is discarded by the filter engine are as follows. These identifiers are constant values in the FWPS_GENERAL_DISCARD_REASON enumeration that is defined in Fwpstypes.h.

Discard reason identifier	Discard reason description
FWPS_DISCARD_FIREWALL_POLICY	An FWP_ACTION_BLOCK action was returned from a filtering decision.
FWPS_DISCARD_IPSEC	Reserved.

Network layer discard reasons

Article • 12/15/2021

The identifiers for the possible reasons that data is discarded by one of the network layers are as follows. These identifiers are constant values in the IP_DISCARD_REASON enumeration that is defined in Fwpsk.h.

Discard reason identifier	Discard reason description
IpDiscardBadSourceAddress	The outgoing packet's source address is a multicast address, a broadcast address, or an IPv6 address that contains an embedded IPv4 loopback or unspecified address.
IpDiscardNotLocallyDestined	The received packet's destination address does not exist on the system, and no appropriate forwarding interface exists.
IpDiscardProtocolUnreachable	There is either no transport protocol handler for the received packet or the transport protocol handler refused to process the packet.
IpDiscardPortUnreachable	There is no application that is receiving packets on the received packet's destination port.
IpDiscardBadLength	A length field specified within the received packet is inconsistent with the packet's length.
IpDiscardMalformedHeader	The received packet contains a recognized extension header or option whose contents are invalid.
IpDiscardNoRoute	The received packet cannot be forwarded to its destination address because the system's routing table does not contain a route to that destination.
IpDiscardBeyondScope	The received packet cannot be forwarded because the packet's incoming and outgoing network interfaces have different zone indexes for the packet's zone level.
IpDiscardInspectionDrop	Reserved for internal use by the network stack.
IpDiscardTooManyDecapsulations	The received packet cannot be forwarded to its destination address because there are too many decapsulations.
IpDiscardAdministrativelyProhibited	Reserved for internal use by the network stack.
IpDiscardHopLimitExceeded	The received packet's hop limit or time-to-live limit has been exceeded.

Discard reason identifier	Discard reason description
IpDiscardAddressUnreachable	The outgoing packet cannot be sent to the packet's destination address either because the destination does not exist or packets are not allowed to be sent to that destination.
IpDiscardRscPacket	The outgoing packet cannot be sent because it is a receive-side coalesced (RSC) packet.
IpDiscardArbitrationUnhandled	Reserved for internal use by the network stack.
IpDiscardInspectionAbsorb	The outgoing packet cannot be sent because WFP took ownership of the packet.
IpDiscardDontFragmentMtuExceeded	Reserved for internal use by the network stack.
IpDiscardBufferLengthExceeded	Reserved for internal use by the network stack.
IpDiscardAddressResolutionTimeout	Reserved for internal use by the network stack.
IpDiscardAddressResolutionFailure	Reserved for internal use by the network stack.
IpDiscardIpsecFailure	Reserved for internal use by the network stack.
IpDiscardExtensionHeadersFailure	Reserved for internal use by the network stack.
IpDiscardAllocationFailure	Reserved for internal use by the network stack.

Transport layer discard reasons

Article • 12/15/2021

The identifiers for the possible reasons that data is discarded by one of the transport layers are as follows. These identifiers are constant values in the INET_DISCARD_REASON enumeration that is defined in Fwpsk.h.

Discard reason identifier	Discard reason description
InetDiscardSourceUnspecified	The outgoing packet's source address is unspecified.
InetDiscardDestinationMulticast	The outgoing packet's destination address is an unspecified address, and the transport does not support multicast addresses.
InetDiscardHeaderInvalid	The packet's transport protocol header is invalid.
InetDiscardChecksumInvalid	The checksum in the packet's transport protocol header is invalid.
InetDiscardEndpointNotFound	The endpoint specified in the packet's header could not be found.
InetDiscardConnectedPath	The packet remote address does not match the remote address of a connected endpoint.
InetDiscardSessionState	The packet cannot be delivered based on network layer information.
InetDiscardReceiveInspection	The connection was closed due to a receive inspection failure.
InetDiscardAckInvalid	The packet is an invalid ACK segment.
InetDiscardExpectedSyn	A SYN segment was expected.
InetDiscardRst	The packet is an invalid RST segment.
InetDiscardSynRcvdSyn	A TCP connection in SYN_RCVD state received another SYN segment.
InetDiscardSimultaneousConnect	A TCP connection has encountered the simultaneous-connect condition.
InetDiscardPawsFailed	A TCP PAWS check failed.

Discard reason identifier	Discard reason description
InetDiscardLandAttack	The packet was detected as part of a Land Attack.
InetDiscardMissedReset	An SYN segment outside the receive window was received on a SYN_RCVD connection. An RST may have been missed.
InetDiscardOutsideWindow	A TCP segment was outside the receive window.
InetDiscardDuplicateSegment	A duplicate TCP segment was received.
InetDiscardClosedWindow	The TCP receive window was closed.
InetDiscardTcbRemoved	The TCP connection was closed.
InetDiscardFinWait2	The TCP connection is closing.
InetDiscardReassemblyConflict	A TCP data reassembly conflict was encountered on reception of a FIN segment.
InetDiscardFinReceived	A FIN was already received on a TCP connection; no more data can be received.
InetDiscardListenerInvalidFlags	A segment with invalid flags was received by a listening TCP socket.
InetDiscardUrgentDeliveryAllocationFailure	There is insufficient memory for URG delivery on a TCP connection.
InetDiscardTcbNotInTcbTable	A TCP connection was closed due to urgent delivery.
InetDiscardTimeWaitTcbReceivedRstOutsideWindow	A TIME_WAIT state TCP connection received an RSP segment outside the window.
InetDiscardTimeWaitTcbSynAndOtherFlags	A TIME_WAIT state TCP connection received a segment with SYN and one or more incompatible flags.
InetDiscardTimeWaitTcb	A TIME_WAIT state TCP connection received an invalid segment.

WFP user mode management functions

Article • 12/15/2021

The semantics of the Windows Filtering Platform user-mode management functions are exactly the same when called from a callout driver as when called from a user-mode application, except that the return type is an **NTSTATUS** code instead of a Win32 error code.

These functions are documented in the Management Functions section of the user-mode WFP Functions documentation.

ⓘ Note

The kernel-mode version of each function is defined in fwpmk.h. The user-mode version of each function is defined in fwpmu.h.

Callers of all of these functions except FwpmFreeMemory0 must be running at IRQL = PASSIVE_LEVEL. Callers of **FwpmFreeMemory0** must be running at IRQL <= DISPATCH_LEVEL.

Callout Management

System Area Networks Overview

Article • 12/15/2021

A *system area network* (SAN) is a group of devices that are linked by a high-speed, high-performance connection. A SAN connection uses Internet Protocol (IP) addresses, which are assigned by TCP/IP to each SAN network interface controller (NIC), to determine data routing. It also uses a reliable transport, which is built into the SAN, to perform data delivery. A SAN can include, for example, clusters of client and server computers.

This section includes:

Supporting System Area Networks

Windows Sockets Direct

Supporting System Area Networks Topics

Article • 12/15/2021

This section describes the performance benefits that client and server computers can achieve by interfacing with a SAN, as well as the software components that you must implement and supply. These matters are discussed in the following topics:

Introduction to System Area Networks

Using a SAN with Windows Sockets Applications

Creating Components for Using a SAN

Virtual Interface Architecture and Support for SAN

Introduction to System Area Networks

Article • 01/29/2022

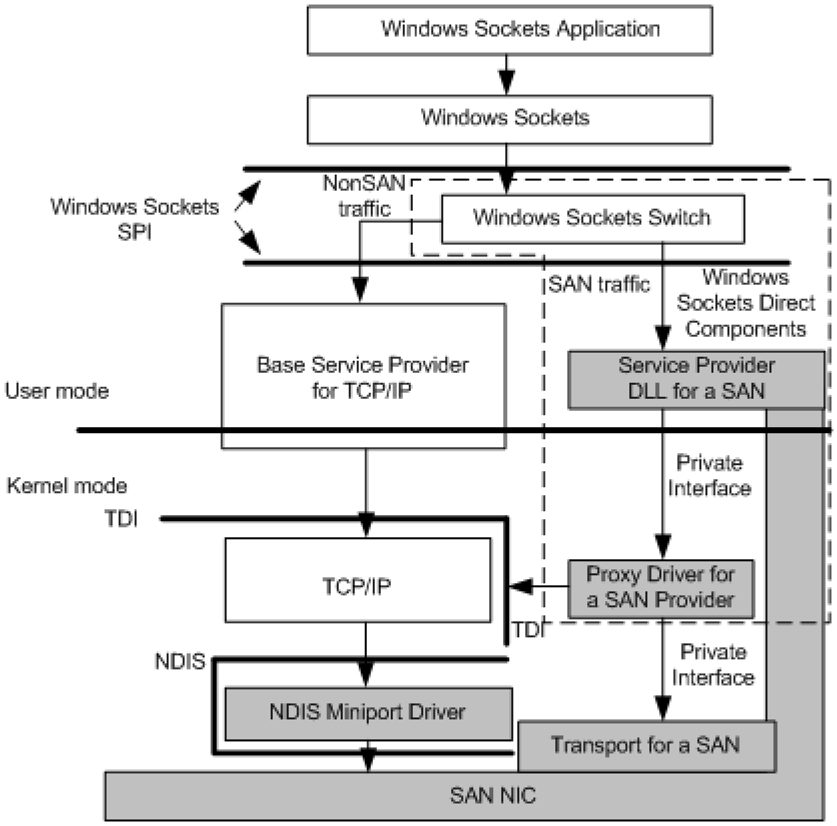
A *system area network (SAN)* is a high-performance, connection-oriented network that can link a cluster of computers. A SAN delivers high bandwidth (1 Gbps or greater) with low latency. A SAN is typically switched by hubs that support eight or more nodes. The cable lengths between nodes on a SAN range from a few meters to a few kilometers.

Unlike existing network technologies such as Ethernet and ATM, a SAN offers a reliable transport service; that is, a SAN guarantees to deliver uncorrupted data in the same order in which it was sent. Connection endpoints in a SAN are not required to use the TCP/IP protocol stack to transfer data unless traffic must be routed between subnets. SAN-local communication can use a native SAN transport, bypassing the TCP/IP protocol stack.

A SAN network interface controller (NIC), a transport driver for the SAN NIC, or a combination of both exposes a private transport interface. However, because most networking applications are written to use TCP/IP through Windows Sockets, they cannot use a SAN directly. The Windows Sockets Direct components shown in the following figure let these applications benefit from using a SAN transparently without requiring modification. Windows Sockets Direct is part of:

- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Advanced Server SP2
- Microsoft Windows 2000 Server Appliance Kit SP2
- Microsoft Windows Server 2003

The following figure shows the architecture required to support a SAN. The shaded areas represent components that a SAN NIC vendor supplies to enable using a SAN.



The following is a description of the components shown in this figure.

Windows Sockets application

Application that interfaces with Windows Sockets for network services.

Windows Sockets

The Windows Sockets interface (Ws2_32.dll).

Windows Sockets SPI

The Windows Sockets service provider interface (SPI).

Windows Sockets switch

The Windows Sockets switches between use of the standard TCP/IP service provider and particular SAN service providers.

TCP/IP service provider

A user-mode DLL and associated kernel-mode proxy driver that comprise the standard base Windows Sockets service provider for TCP/IP. The proxy driver exposes a TDI interface.

TCP/IP

The standard TCP/IP protocol driver.

SAN service provider

The user-mode DLL portion of the SAN service provider.

Proxy driver for a SAN service provider
The kernel-mode proxy driver of the SAN service provider.

NDIS miniport driver
The NDIS miniport driver that supports communication to the SAN NIC using the standard TCP/IP protocol driver.

SAN transport
A reliable transport service, which can be fully implemented in the NIC, fully implemented in software, or implemented in a combination of both hardware and software.

SAN NIC
The physical SAN network interface controller (NIC).

A kernel-mode provider for a particular SAN. (Reserved for future use.)

Using a SAN with Windows Sockets Applications

Creating Components for Using a SAN

Virtual Interface Architecture and Support for SAN

Using a SAN with Windows Sockets Applications

Article • 12/15/2021

Windows Sockets applications can benefit from using a system area network (SAN). These applications can use a SAN to transfer data in bulk form and to drop data directly onto the SAN network, without copying across the user-kernel boundary, using a technology called Windows Sockets Direct. Windows Sockets Direct lets these applications use a SAN transparently.

For each Windows Sockets application, Windows Sockets Direct can either:

- Route data traffic that flows over a SAN directly to the SAN.

  The system-supplied Windows Sockets switch component of Windows Sockets Direct routes data traffic for a SAN that originates from a Windows Sockets application directly to the SAN NIC to be transferred over the SAN network. The switch uses that SAN's particular Windows Sockets service provider to transfer data.

- Route data traffic that flows over other networks through TCP/IP.

  To route data traffic that is not for a specific SAN from a Windows Sockets application, the switch must use the TCP/IP service provider. Non-SAN-specific data traffic includes, for example, datagrams, multicast, and connections that must be routed. Non-SAN-specific data traffic is then routed through TCP/IP and the NDIS miniport driver to the SAN NIC.

Creating Components for Using a SAN

Article • 12/15/2021

Windows Sockets applications can benefit from using a system area network (SAN). To use a SAN, these applications must have a SAN service provider DLL and a proxy driver for that DLL.

To use a specific SAN to transfer data, you also need a reliable transport for that SAN. If a reliable transport is not fully implemented in the SAN NIC hardware, you need a transport driver for the SAN. If required, a SAN transport driver is specified by the SAN NIC vendor and communicates with its overlying SAN proxy driver and underlying SAN NIC through private interfaces.

For information about implementing a SAN service provider DLL and its proxy driver, see Windows Sockets Direct. Note, however, that this section does not specify how to write a SAN transport driver.

You need an NDIS miniport driver to transfer data that must flow over networks other than your specific SAN such as Ethernet, ATM, or another SAN. TCP/IP uses the NDIS miniport driver to send data both to the SAN NIC and over such networks.

For information about implementing miniport and transport drivers, see *Miniport Drivers* and TDI Transports and Their Clients.

Virtual Interface Architecture and Support for SAN

Article • 12/15/2021

The Virtual Interface (VI) architecture, proposed by Compaq, Intel, and Microsoft, is a design for an interface between a SAN NIC and a host computer system. This architecture represents only one aspect of design with regard to system area networks (SAN). There are alternate designs that share the same fundamental characteristics.

The VI architecture defines a set of capabilities and characteristics for SAN interconnects. For example, the VI architecture includes support for remote direct memory access (RDMA) operations. The VI architecture also describes specific mechanisms for interacting with a SAN NIC to manage endpoints and connections, and to process data transfer requests.

The Windows Sockets switch works with a broader class of SAN interconnects beyond those that use the VI architecture. SAN extensions to the Windows Sockets service provider interface (SPI) shield the switch from the hardware interface for a particular SAN NIC. That hardware interface is encapsulated within a SAN service provider DLL and its kernel-mode proxy driver. These components are supplied by a SAN vendor. For more information about SAN extensions, see Windows Sockets SPI Extensions for SANs.

Windows Sockets Direct Overview

Article • 12/15/2021

Microsoft Windows Sockets Direct is a technology that, when possible, routes data at high speed and with high performance to and from Windows Sockets applications through a system area network (SAN) instead of the TCP/IP transport and an NDIS miniport driver.

Windows Sockets Direct is included in:

- Microsoft Windows 2000 Datacenter Server
- Microsoft Windows 2000 Advanced Server SP2
- Microsoft Windows 2000 Server Appliance Kit SP2
- Microsoft Windows Server 2003

The following topics describe Windows Sockets Direct features and operations, the software components that enable Windows Sockets Direct, and the requirements for writing a SAN service provider and its associated proxy driver:

Windows Sockets Direct Architecture

Windows Sockets Direct Component Operation

Creating a Service Provider for a SAN

Creating a Proxy Driver for a SAN Service Provider

Windows Sockets Direct Architecture

Article • 12/15/2021

Windows Sockets Direct provides a high-speed, high-performance connection between two network nodes on the same system area network (SAN) by mapping a SAN transport interface directly into an application process. This SAN connection enables user-mode processes to perform direct input and output (I/O) without copying across the user-kernel boundary.

The SAN architecture figure in Introduction to System Area Networks shows how Windows Sockets Direct provides a SAN connection. The shaded areas in the figure represent components that a SAN NIC vendor must supply to enable use of a SAN.

The following paragraphs describe the components that appear in the figure.

Supplied Components for SAN Network Interface Controllers

Each SAN network interface controller (NIC) uses the following software components to provide support for NDIS and for Windows Sockets Direct.

- An NDIS miniport driver for a SAN NIC provides support for NDIS so that it can communicate with Windows Sockets applications using a standard TCP/IP protocol driver. This NDIS miniport driver supports standard media types such as Ethernet or ATM.

- The SAN service provider DLL and its associated proxy driver provide support for Windows Sockets Direct. These Windows Sockets Direct components export the native transport semantics of an interconnect for the SAN to Windows Sockets applications. These semantics can include, for example, address family and message orientation.

The SAN NIC vendor supplies the NDIS miniport driver and Windows Sockets Direct components. The SAN NIC vendor might also supply a SAN transport driver if transport service is not implemented fully in the NIC. The proxy driver for a SAN service provider DLL and possibly a SAN transport driver are contained either in the NDIS miniport driver or in separate drivers, at the discretion of the SAN NIC vendor.

Windows Sockets Switch Components

The Windows Sockets switch is an operating system-supplied component of Windows Sockets Direct. The switch is a Windows Sockets service provider that is layered on top of TCP/IP and SAN service providers. The Windows operating system inserts the switch between the Windows Sockets interface and the other service providers. For clarity, the switch appears in the figure as a separate entity. However, the switch and the base TCP/IP service provider are actually implemented in the same DLL. The switch performs the following actions:

- Makes the installed collection of SAN service providers and the standard TCP/IP provider look like a single provider to Windows Sockets applications.
- Chooses, on a per-connection basis, whether to use a native SAN service provider or the standard TCP/IP provider to service an application socket.
- Emulates TCP/IP semantics when using a native SAN service provider.

The top and bottom interfaces of the switch conform to the Windows Sockets Service Provider Interface (SPI). The switch's bottom interface uses extensions to the Windows Sockets SPI to take advantage of a SAN's capabilities. Those extensions are described in Windows Sockets SPI Extensions for SANs and fully documented in the Windows Sockets Direct Reference.

The switch manages application access to all networks. A computer can contain multiple SAN NICs from multiple vendors, as well as one or more LAN and WAN NICs, such as a LAN NIC that supports an Ethernet network. The switch manages application access to all networks associated with these NICs transparently.

TCP/IP Functions

As with any NIC exposed through NDIS, the TCP/IP protocol driver assigns one or more IP addresses to each SAN NIC. The Windows Sockets switch and SAN service providers determine these assignments, as described in Receiving and Translating NIC Addresses. The switch uses this IP address information to determine which SAN service provider to use for a given socket connection. SAN service providers use this IP address information to translate IP addresses into native SAN addresses.

The switch works closely with the standard base TCP/IP service provider to obtain functionality that SAN service providers do not support. The TCP/IP service provider supports listening for connections on multiple providers and synchronization across multiple providers.

The TCP/IP service provider also handles all communication over standard LAN and WAN interconnects, raw IP sockets, all UDP sockets, and connections between subnets.

Windows Sockets Direct Component Operation Topics

Article • 12/15/2021

This sections describes Windows Sockets Direct operations, including the operation of the Windows Sockets switch, a SAN service provider, and the SAN service provider's associated proxy driver.

This section includes the following topics:

Installing Windows Sockets Direct Components

Article • 12/15/2021

The following topics describe how Windows Sockets Direct components (that is, the Windows Sockets switch and individual SAN service providers) are installed:

Installing the Windows Sockets Switch

Installing a SAN Service Provider

Installing the Windows Sockets Switch

Article • 12/15/2021

Microsoft Windows installs the Windows Sockets switch as a *layered service provider*, with the Windows Sockets service provider interface (SPI) as both the top and bottom interface. The switch exports the protocol characteristics of TCP/IP just like the TCP/IP service provider. The switch is the first visible TCP/IP provider, which makes the switch the default choice for applications that open sockets for the WSK address families.

Installing a SAN Service Provider

Article • 12/06/2022

A SAN service provider is typically installed as a base Windows Sockets service provider that interfaces with the Windows Sockets switch. Although a SAN service provider can be installed for direct use by an application instead, the Windows Sockets Direct technology does not support using a SAN service provider in this manner. A SAN service provider that is installed for direct use by an application exports its native address family and protocol characteristics rather than those of TCP/IP protocol.

A SAN service provider that is indirectly exposed to applications through the Windows Sockets switch must set the PFL_HIDDEN flag in the **dwProviderFlags** member of the SAN service provider's WSAPROTOCOL_INFOW structure. To install the SAN service provider on the operating system, the SAN service provider's installation mechanism passes this structure in a call to the WSCInstallProvider function. The SAN service provider's installation mechanism can be for example, a setup program or a function exported by the SAN service provider and called by a INF file directive.

The SAN service provider's installation mechanism must add a value of type REG_BINARY to the following key in the registry before the SAN service provider can be detected by the Windows Sockets switch as a base Windows Sockets service provider:

Console

```
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Winsock\
Parameters\TCP on SAN
```

This value contains the binary representation of the value in the **ProviderId** member from the WSAPROTOCOL_INFOW structure. This value registers a SAN service provider with the Windows Sockets switch. This member contains the globally unique identifier (GUID) that the vendor assigned to the SAN service provider.

The vendor can also assign a unique name that represents this GUID, for example:

- Trademarked name of the product
- Unique numeric value
- Textual representation of the GUID

To register a SAN service provider

1. The switch calls the **WSAProviderConfigChange** function to detect Windows Sockets provider installation and removal events.

2. After a new Windows Sockets service provider is installed, the switch calls the **WSCEnumProtocols** function to query the Windows Sockets catalog and the list of SAN service providers in the registry to determine whether the new service provider controls a SAN. For more information about **WSCEnumProtocols**, see the Windows SDK.

3. If the switch detects a new SAN service provider, the switch initializes that service provider as described in Initializing a SAN Service Provider.

4. The switch also calls the following functions of the newly installed SAN service provider after the SAN service provider is initialized to service any existing listening sockets bound to the wildcard IP address (0.0.0.0) (the wildcard IP address implies that the SAN service provider should accept incoming connection requests from all NICs it controls):

   WSPSocket
   Creates a socket

   WSPBind
   Binds the socket to the wildcard IP address

   WSPListen
   Sets the socket to acknowledge and queue incoming connection requests until accepted by the switch

   Note Beginning with Windows Vista, the wildcard IP address 0.0.0.0 is not available. Also beginning with Windows Vista, if the **IPAutoconfigurationEnabled** registry key is set to a value of 0, automatic IP address assignment is disabled, and no IP address is assigned. In this case, the **ipconfig** command line tool will not display an IP address. If the key is set to a nonzero value, an IP address is automatically assigned. This key can be located at the following paths in the registry:

   HKEY_LOCAL_MACHINE\SYSTEM\Current Control Set\Services\Tcpip\Parameters\IPAutoconfigurationEnabled

   HKEY_LOCAL_MACHINE\SYSTEM\Current Control Set\Services\Tcpip\Parameters\Interfaces\*GUID*\IPAutoconfigurationEnabled

Initializing the Use of a SAN

Article • 12/15/2021

The following topics describe how to initialize the use of a SAN:

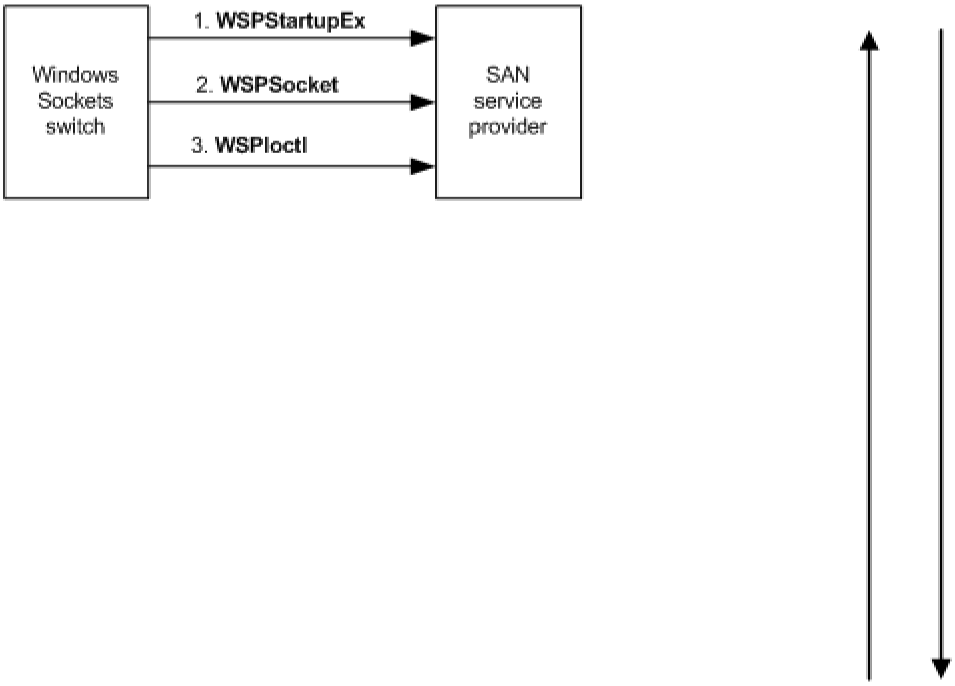
Initializing a SAN Service Provider

Receiving and Translating NIC Addresses

Initializing a SAN Service Provider

Article • 12/06/2022

The Windows Sockets switch initializes a SAN service provider as described in the following figure.



After Windows loads the Windows Sockets switch DLL into an application's process, the following sequence of events occur.

To initialize a SAN service provider

1. The switch detects and loads the TCP/IP provider and then queries the list of SAN service providers in the registry to detect all of those providers, as described in Installing a SAN Service Provider. The switch calls each detected provider's **WSPStartupEx** function to initiate use of that provider.

2. In the **WSPStartupEx** call, the switch passes a pointer to a **WSAPROTOCOL_INFOW** structure that contains the TCP/IP provider's protocol information. The TCP/IP provider's protocol indicates to the SAN service provider that it has been initialized by the switch rather than by other layered service providers or the Windows Sockets interface. The switch passes the TCP/IP provider's protocol information instead of the SAN service provider's transport information, as suggested in the Windows Sockets service provider Interface (SPI) section of the Microsoft Windows SDK documentation.

   Because a SAN service provider can detect that it is initialized by the switch, it can expose the appropriate set of entry-point functions to the switch. If the SAN service provider is initialized directly by an application, it can expose another set of entry-point functions to that application. If a SAN service provider is layered under the switch, that provider must adhere to the extensions and behavior described in this section.

3. A SAN service provider's proxy driver obtains the list of IP addresses assigned to each NIC under its control as described in Registering for SAN NIC Notifications. The SAN service provider uses a private interface to retrieve this list from its proxy driver. The switch calls a SAN service provider's **WSPSocket** function to create a socket. The switch uses this socket to retrieve the complete list of IP addresses assigned to the NICs under control of the SAN service provider's proxy driver. The switch retrieves this list as described in Receiving and Translating NIC Addresses. Based on this list and the lists of other SAN service providers, the switch builds a table that maps local IP subnets to SAN service providers.

4. The Windows Sockets switch must retrieve pointers to the SAN service provider's entry-point functions that extend Windows Sockets service provider Interface (SPI) for use with SANs. To retrieve each of these extended functions, the Windows Sockets switch calls a SAN service provider's **WSPIoctl** function and passes the SIO_GET_EXTENSION_FUNCTION_POINTER command code along with the GUID whose value identifies one of these extended functions.

   For a complete description of these functions, see Windows Sockets SPI Extensions for SANs.

5. The switch can create threads to support listening sockets as well as nonblocking connect requests, as described in Setting Up a SAN Connection.

Receiving and Translating NIC Addresses

Article • 12/15/2021

The Windows Sockets switch always uses the WSK address families, which contain IP addresses, when it interacts with SAN service providers and SAN NICs. The switch does not use a SAN's native address family. Therefore, a SAN service provider must use its associated proxy driver to retrieve the list of IP addresses assigned to its NICs. The SAN service provider uses these IP addresses when interacting with its proxy driver. The proxy driver must translate between IP addresses and native addresses.

During initialization, a proxy driver typically registers with Transport Driver Interface (TDI) for address change notifications. All Plug and Play (PnP) aware transports, including TCP/IP, supply address change notifications through TDI to clients that have registered for such notifications.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Registering for Address Change Notification

During initialization, a proxy driver calls the **TdiRegisterPnPHandlers** function to register for address change notifications. In this call, the proxy driver passes pointers to callback functions for address additions and deletions in the **AddAddressHandlerV2** and **DelAddressHandlerV2** members of the TDI_CLIENT_INTERFACE_INFO structure. After the proxy driver registers to receive these notifications, TDI promptly indicates all currently active network addresses using the add-address callback.

TDI passes the following parameters to a proxy driver's add-address or delete-address callback functions:

Address
Pointer to a TA_ADDRESS structure that describes the network address assigned to or removed from the NIC. In the case of TCP/IP, this pointer is actually a pointer to a TA_ADDRESS_IP structure.

DeviceName
Pointer to a Unicode string that identifies the transport-to-NIC binding with which the address is associated. In case of TCP/IP, the Unicode string has the following format:

\Device\Tcpip_{NIC-GUID}

where NIC-GUID is the globally unique identifier assigned by the network configuration subsystem to the NIC.

The preceding structure definitions are defined in the tdi.h header file. The preceding registration and callback functions are defined in the tdikrnl.h header file. These header files are available in the Microsoft Windows Driver Development Kit (DDK) and the Windows Driver Kit (WDK). Detailed information about TDI PnP notifications is included in TDI Client Callbacks and TDI Client Event and PnP Notification Handlers.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Maintaining a List of IP Addresses

A SAN service provider's proxy driver uses add-address and delete-address notifications to maintain the list of IP addresses assigned to each NIC under its control. The proxy driver uses this list to translate between one or more IP addresses assigned to a SAN NIC by the TCP/IP transport and native SAN addresses. The proxy driver must also supply a device-control routine that makes the list of IP addresses assigned to a NIC available to the Windows Sockets switch whenever the switch makes an SIO_ADDRESS_LIST_QUERY control-code query. The proxy driver's **DriverEntry** routine must specify an entry point for this device-control routine.

The Windows Sockets switch maintains a list of all IP addresses assigned to each SAN NIC. To retrieve IP addresses for this inclusive list, the switch calls each SAN service provider 's **WSPIoctl** function, passing the SIO_ADDRESS_LIST_QUERY control code. Each SAN service provider, in turn, queries its associated proxy driver for its individual list of IP addresses assigned to its SAN NICs. After the switch is notified of an address change, it again queries each SAN service provider for updates in each individual list.

Setting Up a SAN Connection

Article • 12/15/2021

During connection setup, the Windows Sockets switch determines which service provider will service the TCP socket. This provider will handle most subsequent operations on the socket. Regardless of whether the switch chooses a SAN service provider, the TCP/IP provider exclusively handles a few types of setup operations.

This section describes the connection setup operations that a SAN service provider performs and the connection setup operations that the TCP/IP provider handles. This information is provided in the following topics:

Creating and Binding SAN Sockets

Initiating a Connection

Listening for Connections on a SAN

Accepting Connection Requests

Registering Memory for Operations on a SAN

Caching Registered Memory

Creating and Binding SAN Sockets

Article • 12/15/2021

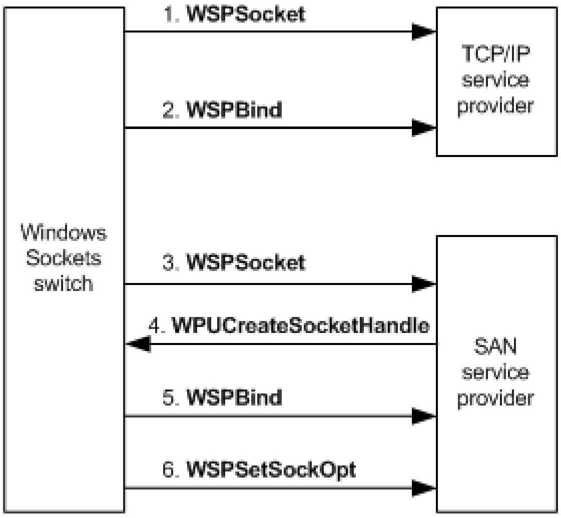
If the Windows Sockets switch determines that it can route data through a SAN connection rather than through the TCP/IP stack, it requests the appropriate SAN service provider to create, bind, and set options for a socket on which the data can be transferred.

The socket created by the SAN service provider is a *companion* to the socket that the TCP/IP service provider created at the request of the application, either from or to which the data is being transferred. The *companion socket* created by the SAN service provider has the same options as the socket created by the TCP/IP service provider, if the SAN service provider supports those options.

The companion socket also has the same IP address and TCP port as the socket that was created by the TCP/IP service provider. The SAN data is transferred through the companion socket created by the SAN service provider rather than the socket created by the TCP/IP service provider. The SAN socket is not visible to the application. From the application's perspective, the data is transferred on the socket that it requested to be created for the data transfer.

Note The switch always uses the TCP/IP service provider to transfer data over *raw sockets*. The switch therefore never requests a SAN service provider to create a raw socket.

The following figure shows an overview of how the Windows Sockets switch creates a companion socket. The sequence in the sections that follow describe creating a companion socket in more detail.



Initiating Creation of a TCP/IP Socket

1. After the Windows Sockets switch receives a **WSPSocket** call that was initiated by an application, the switch calls the TCP/IP provider's **WSPSocket** function to request the TCP/IP provider to create a socket.

2. The Windows Sockets switch returns the descriptor for the created socket to the application and stores this descriptor in a private data structure that is associated with the socket.

   From the application's perspective, the socket created by the TCP/IP provider is the socket used for data transfers, whether the switch uses the TCP/IP service provider or the SAN service provider to transfer the data.

Binding a TCP/IP Socket

1. The switch receives a **WSPBind** call if an application requests to bind the socket to a specific network interface controller (NIC) or to the wildcard IP address (0.0.0.0). A socket bound to the wildcard IP address can listen for incoming connection requests from all NICs.

   Note Beginning with Windows Vista, the wildcard IP address 0.0.0.0 is not available. Also beginning with Windows Vista, if the **IPAutoconfigurationEnabled** registry key is set to a value of 0, automatic IP address assignment is disabled, and no IP address is assigned. In this case, the **ipconfig** command line tool will not display an IP address. If the key is set to a nonzero value, an IP address is automatically assigned. This key can be located at the following paths in the registry:

   HKEY_LOCAL_MACHINE\SYSTEM\Current Control Set\Services\Tcpip\Parameters\IPAutoconfigurationEnabled

   HKEY_LOCAL_MACHINE\SYSTEM\Current Control Set\Services\Tcpip\Parameters\Interfaces\*GUID*\IPAutoconfigurationEnabled

2. The switch forwards this call to the TCP/IP service provider by calling the TCP/IP provider's **WSPBind** function.

Service Provider Determination

1. The switch determines whether to use a SAN service provider for data transfer on a socket after the application initiates a **WSPListen** or **WSPConnect** call to the switch, as described in Setting Up a SAN Connection.

2. If the switch determines that it cannot use a SAN service provider for a data transfer, the switch routes the data transfer through the TCP/IP service provider.

3. If the switch chooses a SAN service provider to service an application's socket, the switch calls the SAN service provider's WSPSocket function to create a companion socket.

Initiating Creation of a Companion Socket

1. The SAN service provider's **WSPSocket** function initializes an internal data structure in which it stores information about the companion socket.

2. The SAN service provider's **WSPSocket** function must next call the **WPUCreateSocketHandle** function to acquire a socket descriptor from the switch.

3. The SAN service provider must store the switch's socket descriptor in its internal data structure for the companion socket and must return its own descriptor for the companion socket to complete the **WSPSocket** call. The socket descriptor returned by the SAN service provider can be any meaningful value, such as a pointer to a private data structure.

4. To perform an operation on the socket, the switch supplies the socket descriptor that was returned by the SAN service provider to the appropriate function of the SAN service provider. Similarly, the SAN service provider must supply the socket descriptor that was acquired from the switch in the **WPUCreateSocketHandle** call if the SAN service provider makes any of the following up calls:

   WPUQuerySocketHandleContext

   WPUCloseSocketHandle

   WPUCompleteOverlappedRequest

Binding a Companion Socket

1. If a SAN service provider's **WSPSocket** function completes successfully, the switch immediately calls the SAN service provider's WSPBind function to assign a local IP address and TCP port to the socket.

2. The switch assigns the same IP address and TCP port to the SAN socket as was assigned to the socket that was created by the TCP/IP provider. The SAN service provider must translate this TCP/IP address into its native format.

3. The switch supplies a fully qualified IP address and TCP port (that is, nonzero values) to the SAN service provider's **WSPBind** function unless an application requested to listen for incoming connections from all NICs. In the later case, the switch supplies the wildcard IP address to the SAN service provider's **WSPBind** function.

Setting Options for a Companion Socket

- If the application specified any socket options, the switch stores those options. After creating the SAN socket, the switch calls the SAN service provider's WSPSetSockOpt function for each supported option that was specified by the application to immediately set these options for the SAN socket.

Failing a Companion Socket Call

- If a SAN service provider fails any of the preceding calls to its **WSPSocket**, **WSPBind**, or **WSPSetSockOpt** functions, the switch calls the SAN service provider's WSPCloseSocket function to destroy the SAN socket. The switch then uses the TCP/IP provider to continue servicing the application socket. Note that, after the switch establishes a connection using a SAN service provider, the switch cannot use the TCP/IP provider to service the application's socket. In this case, the switch returns the appropriate error to the application.

Connecting the Companion Socket

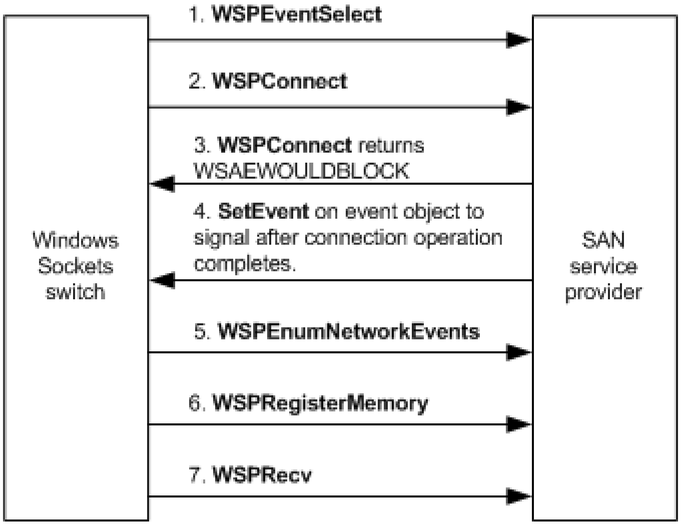
- After the switch sets up the companion socket, the switch calls either the **WSPListen** or **WSPConnect** function for the SAN service provider to perform the operation that caused the SAN service provider to originally set up the socket. For example, if an application originally requested to listen for incoming connections, the switch calls the SAN service provider's WSPListen function.

Initiating a Connection

Article • 12/15/2021

After the Windows Sockets switch receives a **WSPConnect** call that was initiated by an application, the switch compares the destination address of the connect request with addresses in the switch's table of IP subnets that SAN service providers serve. If one of those subnets includes this destination address, the switch calls the **WSPSocket** and **WSPBind** functions of the corresponding SAN service provider to create and bind a socket, as described in Creating and Binding SAN Sockets. The switch processes the application's connect request using the SAN socket. If the destination address of the connect request is not on a SAN subnet, or if the SAN service provider fails to create and bind a socket, the switch uses the TCP/IP provider to establish the connection.

The following figure shows an overview of how the Windows Sockets switch requests a connection with a remote peer. The sequence and sections that follow describe the connection request in more detail.



After creating and binding the SAN socket, the switch executes a connect request, using the SAN socket in *nonblocking mode*, as described in the following procedure.

To execute a connect request

1. The switch calls the SAN service provider's **WSPEventSelect** function. In this call, the switch passes the FD_CONNECT code and the event object to be associated with that code. The call to **WSPEventSelect** requests notification of connection events and informs the SAN service provider that any subsequent **WSPConnect** call executes in nonblocking mode.

2. After the **WSPEventSelect** function returns, the switch calls the SAN service provider's **WSPConnect** function. In this call, the switch passes the destination

address in the format of one of the WSK address families. The SAN service provider's proxy driver maps this destination address to a native address and attempts to establish the connection.

3. If the SAN service provider's **WSPConnect** function can complete or fail the connection operation immediately, it returns the appropriate success or failure code. If the SAN service provider's **WSPConnect** function cannot complete a connection request immediately, the SAN service provider's connection operation proceeds asynchronously in another thread. The SAN service provider's **WSPConnect** function returns with the error WSAEWOULDBLOCK to indicate that the socket is marked as nonblocking and that the connection operation cannot be completed immediately.

4. After the connection operation completes, the SAN service provider calls the Win32 **SetEvent** function to signal the event object that was previously registered in the **WSPEventSelect** call.

5. After the event object is signaled, the switch calls the SAN service provider's **WSPEnumNetworkEvents** function to obtain the result of the connection operation.

Note After the switch establishes a connection through a SAN service provider, the switch can no longer use the TCP/IP provider for that connection. SAN service providers must fully implement all functionality required to service an established connection.

Destroying the SAN Socket

If the SAN service provider's **WSPConnect** function fails, the switch calls the SAN service provider's **WSPCloseSocket** function to destroy the SAN socket. The switch then calls the TCP/IP service provider's **WSPConnect** function to forward the connection operation to the TCP/IP service provider unless the SAN service provider returned one of the following error codes as the result of its connection operation:

WSAECONNRESET
Indicates that no application is listening on the specified port at the destination address

WSAECONNREFUSED
Indicates that the remote application actively refused the connection request

WSAEHOSTUNREACH
Indicates that the destination address does not exist

These preceding error codes guarantee that an attempt to establish the connection through TCP/IP will also fail. A SAN service provider must not return one of these error codes if it cannot make that guarantee. For example, if a target computer that does not support Windows Sockets Direct exists on the SAN but can only communicate through NDIS, the SAN service provider cannot return WSAEHOSTUNREACH as the result of a failed SAN connection request to this target because a connection request through the TCP/IP provider might succeed. In this case, the SAN service provider should return WSAETIMEDOUT.

Session Negotiation

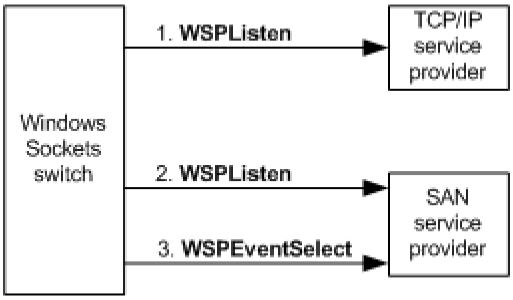
After the switch establishes a connection through a SAN service provider, the switch calls the SAN service provider's **WSPRegisterMemory** extension function to preregister the memory for the buffer array that is to receive incoming messages. The switch next calls the SAN service provider's **WSPRecv** function to post one or more buffers to receive incoming message data from the remote peer. The switch then negotiates a session with its remote peer by exchanging a pair of messages that contain initial flow control information. After the switch negotiates a session, it completes the **WSPConnect** call that the application initiated. The application can then begin sending and receiving data on the connection. For more information, see Accepting Connection Requests.

After a connection is established over a SAN socket, the switch does not call the SAN service provider's **WSPConnect** function. The switch internally handles applications that initiate a call to the switch's **WSPConnect** function to poll for connection requests.

Listening for Connections on a SAN

Article • 12/15/2021

The following figure shows an overview of how the Windows Sockets switch sets a SAN socket to acknowledge and queue--that is, listen for--incoming connection requests from a remote peer. The topics that follow describe the listening process in more detail.



When the Windows Sockets switch receives a **WSPListen** call that was initiated by an application, the switch always calls the TCP/IP provider's **WSPListen** function first to set the TCP/IP provider's socket to acknowledge and queue incoming connection requests. If the application's socket is bound to the IP address of a SAN NIC or to the wildcard IP address, the switch also uses the appropriate SAN service provider to create and bind an additional socket. For more information, see Creating and Binding SAN Sockets.

Listening for Incoming Connection Requests

After requesting a SAN service provider to create and bind the SAN socket, the switch calls the **WSPListen** function of the SAN service provider to cause the SAN socket to listen for incoming connections and to specify a limit on the number of incoming connection requests that the SAN service provider can queue.

Setting Up to Accept Incoming Connections

The switch accepts incoming connections only in nonblocking mode. The switch calls the SAN service provider's **WSPEventSelect** function to put a socket in nonblocking mode and to request notification of incoming connection events. In this call, the switch passes the FD_ACCEPT code and the event object to be associated with that code. After the SAN service provider receives a connection request on its socket that was previously established for listening, the SAN service provider calls the Win32 **SetEvent** function to signal the associated event object. The switch listens for incoming connection events in a dedicated thread and accepts or rejects the connection after the event object is signaled. For more information, see Accepting Connection Requests.

Indicating Refusal of a Connection Request to a Remote Peer

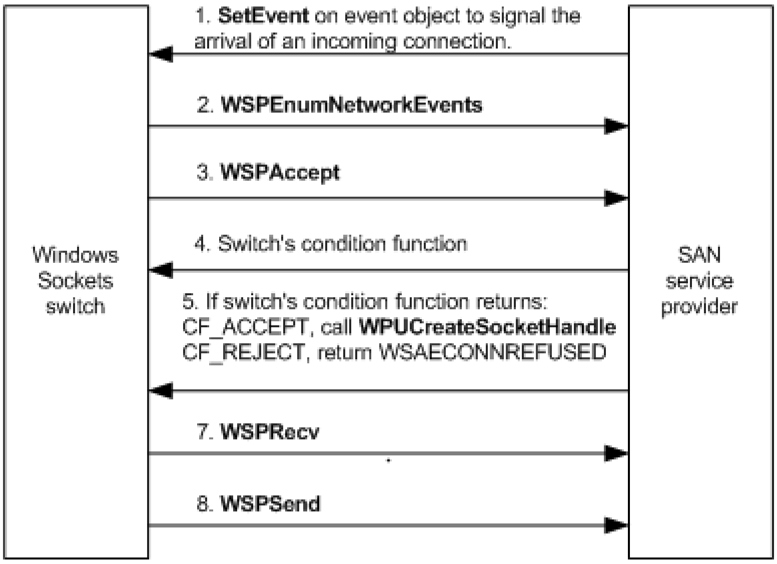
If a connection request arrives and the SAN service provider's backlog of connection requests is full, the SAN service provider should immediately indicate to the remote peer that it refuses the connection request. In this case, the SAN service provider does not signal the event object to inform the switch to accept or reject the connection request. The SAN service provider on the remote peer must then fail its connection operation that was initiated by a **WSPConnect** call with the WSAECONNREFUSED error code.

Accepting Connection Requests

Article • 12/15/2021

If an application calls the **WSAAccept**, **accept**, or **AcceptEx** function to accept an incoming connection request on a socket, the Windows Sockets switch always forwards this call to the TCP/IP service provider. If an incoming connection request arrives from a non-SAN network, it flows through the NDIS path and the TCP/IP service provider handles it. If a connection request arrives from a remote peer on a SAN, the switch acts as an intermediary between the TCP/IP service provider and the SAN service provider in determining whether to accept the connection request and in completing the application's **WSAAccept**, **accept**, or **AcceptEx** function.

The following figure shows an overview of the interaction between the Windows Sockets switch and the SAN service provider in determining whether to accept or reject an incoming connection request. The sequences and sections that follow describe acceptance determination in more detail.



1. **SetEvent** on event object to signal the arrival of an incoming connection.
2. **WSPEnumNetworkEvents**
3. **WSPAccept**
Windows Sockets switch
4. Switch's condition function
SAN service provider
5. If switch's condition function returns:
CF_ACCEPT, call **WPUCreateSocketHandle**
CF_REJECT, return WSAECONNREFUSED
7. **WSPRecv**
8. **WSPSend**

To accept or reject a connect request

1. On receiving an incoming connection request from a remote peer, the SAN service provider signals an event object as described in Listening for Connections on a SAN.

2. The Windows Sockets switch calls the SAN service provider's **WSPEnumNetworkEvents** function to receive the FD_ACCEPT event code.

3. On receiving the FD_ACCEPT event code, the switch calls the SAN service provider's **WSPAccept** function to accept or reject the incoming connection request.

4. In the switch's call to the SAN service provider's WSPAccept function, the switch specifies a condition function. The SAN service provider must call this condition function in the same thread in which the **WSPAccept** function was called before returning from the **WSPAccept** call.

5. The switch returns the CF_ACCEPT or CF_REJECT code from this condition function to indicate that it accepts or rejects the connection request, respectively.

Accepting a Connection Request and Creating an Accepting Socket

If an application accepts an incoming connection request, the switch returns the CF_ACCEPT code to the SAN service provider to complete the switch's condition function. On receiving CF_ACCEPT, the SAN service provider initializes an internal data structure in which it stores information about the accepting socket. The SAN service provider's WSPAccept function must next call the **WPUCreateSocketHandle** function to acquire a descriptor for the accepting socket from the switch. The SAN service provider must store the switch's descriptor in its internal data structure for the accepting socket and must return its own descriptor for the accepting socket to complete the **WSPAccept** call. The switch must supply the SAN service provider's internal descriptor for the accepting socket when calling the SAN service provider's functions, while the SAN service provider must supply the switch's socket descriptor in up calls to the switch.

Before successfully completing WSPAccept, the SAN service provider should call the Win32 **ResetEvent** function to reset the event object. Doing so enables the SAN service provider to later call the Win32 **SetEvent** function to signal the switch to accept the next incoming connection request.

Rejecting a Connection Request

If an application rejects an incoming connection request, the switch returns the CF_REJECT code to the SAN service provider to complete the switch's condition function. On receiving CF_REJECT, the SAN service provider should return the WSAECONNREFUSED error code to the switch to complete the WSPAccept call.

Indicating Acceptance or Refusal of a Connection Request to a Remote Peer

Before a SAN service provider can indicate to a remote peer that it accepts or refuses the remote peer's connection request, the SAN service provider must call the switch's condition function. Depending on the value that the switch's condition function returns, the SAN service provider should make one of the following indications to the remote peer:

If the switch's condition function returns CF_ACCEPT, the SAN service provider should indicate that it accepts the remote peer's connection request. The SAN service provider on the remote peer can then successfully complete its connection operation that was initiated by a **WSPConnect** call.

If the switch's condition function returns CF_REJECT, the SAN service provider should indicate that it refuses the remote peer's connection request. The SAN service provider on the remote peer must fail its connection operation that was initiated by a **WSPConnect** call with the WSAECONNREFUSED error code.

Session Negotiation

After the switch has successfully used a SAN service provider to accept a connection request from a remote peer, the switch negotiates a session with that peer.

To negotiate a session

1. The switch at the remote peer calls the SAN service provider's **WSPRecv** function to post a set of receive buffers.

2. The switch at the remote peer calls the SAN service provider's **WSPSend** function to send a session negotiation message to the switch at the local accepting endpoint. This message includes the number of receive buffers that the switch at the remote peer posted.

3. The switch at the local accepting endpoint calls the local SAN service provider's **WSPRecv** function to post its own receive buffers, but it might not be able to do so in time to receive the session negotiation message. If the local switch does not post a receive buffer in time and if the underlying NIC does not support flow control, the SAN service provider at the local accepting endpoint must buffer the remote switch's session negotiation message in its own private receive buffers. When the switch posts receive buffers, the SAN service provider copies data from its private receive buffers to the switch buffers on a one-to-one basis until all of the data has been copied from the private buffers to the switch buffers.

   The SAN service provider performs normal receive processing on subsequent switch buffers--that is, it posts all such switch buffers to the receive queue on the NIC.

Note that a SAN service provider must not drop a connection simply because the switch did not post a receive buffer before the session negotiation message arrived. The maximum length of a session negotiation message is 256 bytes.

4. The switch at the local accepting endpoint posts its receive buffers before responding to the session negotiation message. The local switch calls the local SAN service provider's WSPSend function to respond to the session negotiation message. The local switch's response includes the number of receive buffers that the local switch posted. From this point forward, the local switch guarantees that the posted set of receive buffers is of sufficient size to receive any message that arrives on the connection.

5. If an application specifies an initial receive buffer in its **AcceptEx** call, the switch waits until it receives the first data message from its remote peer before completing the application's **AcceptEx** call.

6. If the application cancels its own **accept** call, the switch calls the appropriate SAN service provider's WSPCloseSocket function to close the accepting SAN socket.

Registering Memory for Operations on a SAN

Article • 12/15/2021

The Windows Sockets switch calls a SAN service provider's extension functions to register all data buffers for sending and receiving messages and for RDMA operations on a system area network. These extension functions register a buffer to a region of physical memory for use on a particular SAN socket that is connected to a remote peer. For a description of these extension functions, see the Windows Sockets SPI Extensions for SANs.

Registering Data Buffers

The switch calls a SAN service provider's **WSPRegisterMemory** extension function on behalf of an application that runs in a local process to register data buffers that can be accessed only by that process. The buffer handles that **WSPRegisterMemory** returns are valid only in the context of the local process that performed the registration. The switch calls **WSPRegisterMemory** to register buffers that serve as the message receiving buffer in a call to the **WSPRecv** function or the message sending buffer in a call to the **WSPSend** function. The switch also calls **WSPRegisterMemory** to register buffers that serve as the local receiving RDMA buffer in a call to the **WSPRdmaRead** extension function or the local RDMA source in a call to the **WSPRdmaWrite** extension function. After the local process finishes using buffers that were registered with **WSPRegisterMemory**, the switch calls the **WSPDeregisterMemory** extension function to release those buffers.

The switch calls the SAN service provider's **WSPRegisterRdmaMemory** extension function on behalf of an application that runs in a local process to register RDMA buffers that both local and remote processes can access. The buffer descriptors that **WSPRegisterRdmaMemory** returns are valid only for RDMA data transfer operations that a remote peer initiates in the context of the peer's connection to the SAN socket on which the registration was performed. The switch at the remote peer connection uses these RDMA buffers as either the target in a call to the **WSPRdmaWrite** extension function or the source in a call to the **WSPRdmaRead** extension function. After the local and remote processes finish using buffers that were registered with **WSPRegisterRdmaMemory**, the switch calls the **WSPDeregisterRdmaMemory** extension function to release those buffers.

Managing Memory Access

A SAN service provider must prevent unauthorized access to registered memory.

Memory must be registered and accessible as follows:

Memory registered for local access should be available only to the process in which the switch called **WSPRegisterMemory**.

Memory registered for both local and remote access can be accessed by either the process in which the switch called **WSPRegisterRdmaMemory** to register memory, or by the remote peer that is connected to the SAN socket to which the memory is registered.

Memory must be accessible only while registered and while the connection is established. A SAN service provider must ensure that it does not inadvertently make such memory accessible to other processes running on the same computer or on other computers on the SAN.

Memory registered only for read access must not be available for write access. Memory registered only for write access must not be available for read access.

Using Registered Memory

The switch registers two virtually contiguous regions of memory for each connected TCP socket to use for negotiating a data-transfer session. The switch uses one region of memory to provide message buffers containing send data when calling a SAN service provider's **WSPSend** function. The switch uses the other region of memory to post message buffers to receive data when calling a SAN service provider's **WSPRecv** function.

The switch typically registers RDMA buffers only if it transfers application data in RDMA operations.

Before the switch closes a socket, the switch calls either **WSPDeregisterMemory** or **WSPDeregisterRdmaMemory** functions of a SAN service provider to release any memory that a pending data transfer operation is not currently using. The SAN service provider must also release memory associated with outstanding data transfer operations.

Caching Registered Memory

Article • 12/06/2022

SAN service providers can cache RDMA buffers that are exposed for either local or remote access to improve performance.

Caching RDMA Buffers Exposed for Local Access

The Windows Sockets switch calls a SAN service provider's WSPRegisterMemory extension function on behalf of an application to register all data buffers that serve as either the local receiving RDMA buffer in a call to the WSPRdmaRead extension function or the local RDMA source in a call to the WSPRdmaWrite extension function. As part of this registration process, the SAN service provider must lock down these buffers to regions of physical memory and register them with the SAN NIC. Both of these operations are resource intensive. Therefore, the SAN service provider should use caching to reduce the overhead of these registrations. If the SAN service provider uses caching, the performance of applications that reuse buffers for data transfers improves.

SAN service providers should cache and release RDMA buffers that are exposed for local access as described in the following list:

1. When the switch calls the WSPDeregisterMemory extension function to release a buffer, the SAN service provider should leave the buffer registered with the SAN NIC and locked down to a region of physical memory. The SAN service provider should also add the buffer to a cache of registered buffers, in case the buffer is used again in a subsequent RDMA operation, and secure possession of the buffer as described in the next list item.

2. A SAN service provider caches memory registrations based on virtual addresses. When the SAN service provider caches a buffer's registration, the SAN service provider's proxy driver must call the MmSecureVirtualMemory function to secure possession of that registered buffer so that the operating system notifies the switch if the buffer is released (for example, if an application calls the VirtualFree function to release a virtual address range back to the operating system).

3. When the switch subsequently calls **WSPRegisterMemory** to register a buffer, the SAN service provider should check its cache to determine if the buffer is already registered. If the SAN service provider finds the buffer in its cache, the SAN service provider should not perform any further registration action.

4. Before the virtual-to-physical mappings of the registered buffer subsequently change, the switch calls each SAN service provider's **WSPMemoryRegistrationCacheCallback** extension function. Each SAN service provider's proxy driver, in turn, must call the **MmUnsecureVirtualMemory** function to release ownership of the buffer. In addition, each SAN service provider must remove the buffer from its cache and must remove the buffer registration from the SAN NIC.

5. Before the connection between a local SAN socket and a remote peer is closed, the SAN service provider should release any cached buffers.

Note The proxy driver must use the **try/except** mechanism around code that accesses a user-mode buffer that was secured through a call to **MmSecureVirtualMemory** to prevent operating system crashes. For more information about how a proxy driver secures and releases buffers, see Securing and Releasing Ownership of Virtual Addresses.

Caching RDMA Buffers Exposed for Remote Access

The Windows Sockets switch calls a SAN service provider's **WSPRegisterRdmaMemory** extension function to register all data buffers that serve as either the remote RDMA target of a remote **WSPRdmaWrite** call or the remote RDMA source of a remote **WSPRdmaRead** call. That is, the switch exposes these buffers for access by a remote peer. After data transfers from these buffers are completed, the switch calls the SAN service provider's **WSPDeregisterRdmaMemory** extension function to release these buffers so that they are no longer accessible from the remote peer.

SAN service providers should cache RDMA buffers that are exposed for remote access as described in the following list:

1. When the Switch calls **WSPDeregisterRdmaMemory** to release a buffer, the SAN service provider should leave the buffer locked in physical memory and registered with the SAN NIC. The SAN service provider should also add the buffer to a cache of registered buffers, in case the buffer is used again in a subsequent RDMA operation. However, the SAN service provider should take appropriate action to ensure that the remote peer can no longer access the buffer. **Note** If the buffer can only be made inaccessible by the SAN service provider removing the buffer registration from the SAN NIC, the SAN service provider must do so. However, the SAN service provider should leave the buffer locked down to a region of physical memory. This scenario does not provide the best possible performance but is better than no caching.

2. To cache RDMA buffers exposed for remote access, the SAN service provider and its proxy driver should use the caching techniques as described in the preceding list for RDMA buffers that are exposed for local access.

3. When the switch subsequently calls **WSPRegisterRdmaMemory** to register a buffer, the SAN service provider should check its cache to determine if the buffer is already registered. If the SAN service provider finds the buffer in its cache, the SAN service provider should simply expose the buffer for remote access, no further registration action is required. However, if the buffer registration was previously removed from the SAN NIC, the SAN service provider should register the buffer again.

4. To release RDMA buffers exposed for remote access, the SAN service provider and its proxy driver should use the techniques as described in the preceding list.

Transferring Data on a SAN

Article • 12/15/2021

Many system area networks (SANs) lack flow control; therefore, the Windows Sockets switch uses a lightweight session protocol to transfer data on a SAN. The following topics describe features of the switch's session protocol that enable data transfer operations for a SAN service provider:

Using Session Protocol

Sending Urgent Data on a SAN

Completing Data Transfer Requests

Using Session Protocol

Article • 12/15/2021

The Windows Sockets switch uses its session protocol to transfer data over a SAN connection. If the switch transfers a small amount of data, it transfers that data within a control message. Each control message consists of a header and an optional payload of application data. If the switch transfers a large amount of data, it transfers that data using RDMA operations.

This section describes how to set up and perform a data transfer.

Note Depending on the behavior of applications that load the switch, the switch optimizes its session protocol to reduce the overhead involved in transferring application data.

This section also provides examples of how the switch's session protocol performs data transfers. However, these examples do not include definitive descriptions of these operations.

Setting Up a Data Transfer

The switch allocates a pool of control message buffers for each connected socket. The switch then makes calls to the SAN service provider's **WSPRegisterMemory** function to register those message buffers to regions of physical memory. The switch uses part of the buffer pool to send flow control information to a remote peer when calling a SAN service provider's **WSPSend** function. The switch uses the other part of the pool to post message buffers to receive flow control information from a remote peer when calling a SAN service provider's **WSPRecv** function. After the switch receives control messages, it immediately consumes them. After consuming control messages, the switch calls the SAN service provider's **WSPRecv** function and passes receive buffers to post them again so they can receive additional control messages from a remote peer.

Transferring Application Data

The size of the data transfer affects how the switch will handle the data transfer operation.

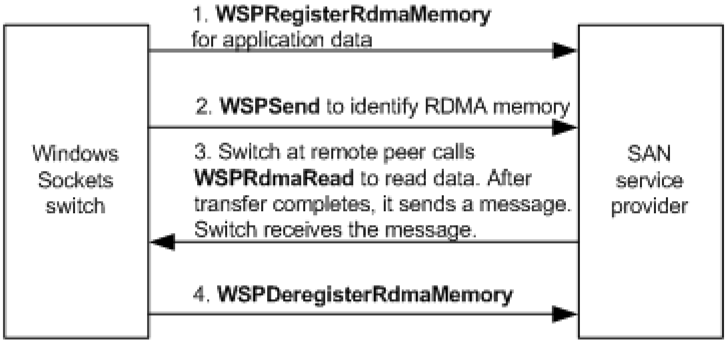
If an application requests to send a small amount of data, the switch transfers that data as described in Sending Urgent Data on a SAN.

If an application requests to send a large amount of data, the switch copies the initial portion of the data to a control message buffer that is used for sending. The header for this control message contains information that specifies the amount of application data. The switch then calls the SAN service provider's WSPSend function to send this control message to the SAN socket's remote peer.

How the switch completes the transfer of application data depends on whether the service provider supports the WSPRdmaRead function.

Data Transfer to a Provider That Supports the WSPRdmaRead Function

The following figure shows an overview of how the switch completes the transfer of application data if the SAN service provider at the remote peer supports a WSPRdmaRead function. The sequence that follows describes transferring application data in more detail.



Windows Sockets switch
1. WSPRegisterRdmaMemory for application data
2. WSPSend to identify RDMA memory
3. Switch at remote peer calls WSPRdmaRead to read data. After transfer completes, it sends a message. Switch receives the message.
4. WSPDeregisterRdmaMemory
SAN service provider

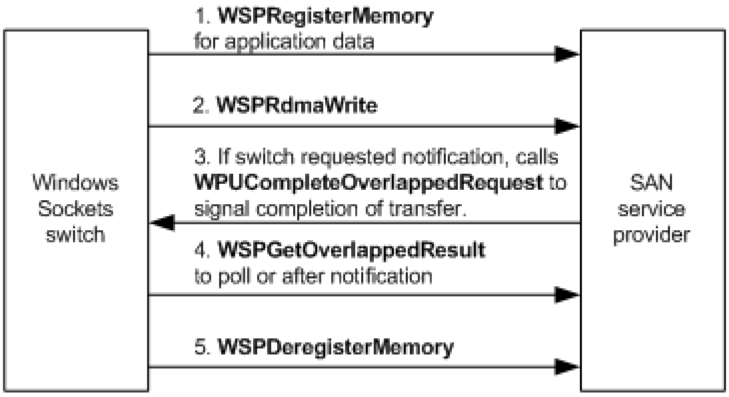
To transfer data when the remote peer supports WSPRdmaRead

- The local switch must call the SAN service provider's WSPRegisterRdmaMemory function to register RDMA memory for read access. In this case, the control header for the message buffer also identifies the descriptor for the RDMA memory that holds the application's remaining data.
- The switch at the remote peer then calls WSPRdmaRead to transfer application data from RDMA memory to receiving buffers that the switch at the remote peer previously registered with WSPRegisterMemory calls. The SAN service provider transmits the buffered data in the background. Doing so allows applications that do not post more than one send at a time to post another send request while the SAN service provider sends buffered data.
- The switch at the remote peer then calls WSPSend to send a control message to the local switch to indicate that the transfer is complete.

- The local switch calls the WSPDeregisterRdmaMemory function to release RDMA memory.
- The local switch completes the application's send request. If the switch cannot register memory for the application's data buffers or if temporary memory cannot be fully allocated, it completes an application's send request with the **WSAENOBUFS** error code.

Data Transfer to a Provider That Does Not Support the WSPRdmaRead Function

The following figure shows an overview of how the switch completes the transfer of application data if the SAN service provider at the remote peer does not support a WSPRdmaRead function. The sequence that follows describes transferring application data in more detail.



1. WSPRegisterMemory
for application data
2. WSPRdmaWrite
3. If switch requested notification, calls
WPUCompleteOverlappedRequest to
signal completion of transfer.
Windows
Sockets
switch
4. WSPGetOverlappedResult
to poll or after notification
SAN
service
provider
5. WSPDeregisterMemory

To transfer data when the remote peer does not support WSPRdmaRead

- The switch at the remote peer calls **WSPRegisterRdmaMemory** to register RDMA memory for write access.
- The switch at the remote peer then calls **WSPSend** to send a control message to the local switch that indicates the location of RDMA memory to which the local switch can write.
- The local switch calls the **WSPRdmaWrite** function to transfer application data to the RDMA memory. The SAN service provider transmits the buffered data in the background. Doing so allows applications that do not post more than one send at a time to post another send request while the SAN service provider sends buffered data.
- The local switch calls the **WSPGetOverlappedResult** function to obtain the results of the transfer. For more information, see Completing Data Transfer Requests.

- The local switch calls WSPSend to send a control message to the remote peer to indicate that the transfer is complete.
- The switch at the remote peer calls WSPDeregisterRdmaMemory to release RDMA memory.
- The local switch completes the application's send request. If the switch cannot register memory for the application's data buffers or if temporary memory cannot be allocated, it completes an application's send request with the **WSAENOBUFS** error code.

Transferring Data on a SAN

Sending Urgent Data on a SAN

Article • 12/15/2021

If an application sends urgent data on a SAN, the Windows Sockets switch transfers that data as described in the following sequence:

1. For requests to send urgent data, the switch receives a **WSPSend** call in which the MSG_OOB flag is set.

2. The switch copies the urgent data to the payload portion of a control message buffer.

3. The switch calls the appropriate SAN service provider's **WSPSend** function to transmit the urgent data contained in the control message to the remote peer connection for a SAN socket. The SAN NIC in turn transmits the urgent data.

4. The switch at the remote peer receives the transmitted data into receive buffers that it posted with the **WSPRecv** function.

5. The switch at the remote peer copies the received data from the receive buffers to private storage.

6. The switch at the remote peer calls **WSPRecv** to repost the receive buffers.

7. The switch at the remote peer delivers the data to an application in accordance with standard Windows Sockets procedures.

Completing Data Transfer Requests

Article • 12/06/2022

The Windows Sockets switch transfers data on a SAN socket asynchronously. Whenever the switch calls the SAN service provider's **WSPSend**, **WSPRecv**, **WSPRdmaWrite**, or **WSPRdmaRead** data-transfer function, it specifies a pointer to an overlapped structure (WSAOVERLAPPED) and **NULL** for a completion routine. Even if the switch calls the SAN service provider's **WSPEventSelect** function to indicate that the socket is in nonblocking mode, the SAN service provider is not required to implement nonblocking semantics for these data-transfer functions.

As described in the Windows Sockets API and SPI documentation in the Microsoft Windows SDK documentation, both blocking and nonblocking sockets treat overlapped operations the same. That is, the SAN service provider starts the particular data transfer operation and then immediately returns control to the switch. These data-transfer functions return error code WSA_IO_PENDING to indicate that an asynchronous operation started and that completion of that operation occurs later. After the operation completes, the SAN service provider signals completion if the switch requires completion notification as described in following paragraphs.

Because the switch always specifies **NULL** for a completion routine for overlapped data transfer operations, a SAN service provider is not required to support completion through the use of asynchronous procedure calls (APCs).

Whenever possible, the switch attempts to call the SAN service provider's **WSPGetOverlappedResult** function to poll for completion of data transfer requests. In this way, the switch can avoid the overhead associated with active overlapped completion mechanisms. To indicate to a SAN service provider that the switch does not require completion notification for a particular overlapped data transfer operation, the switch sets the low-order bit of the **hEvent** member in the **WSAOVERLAPPED** structure to one. The SAN service provider must not notify the switch of the completion of requests submitted in this manner.

If the switch requires notification of the completion of an overlapped data transfer operation, it sets the low-order bit of the **hEvent** member in the WSAOVERLAPPED structure to zero. The SAN service provider must complete data transfer operations that are initiated in this way by calling the **WPUCompleteOverlappedRequest** function to signal completion. In this call, the SAN service provider passes a pointer to the WSAOVERLAPPED structure that corresponds to a completed data transfer operation. In this **WPUCompleteOverlappedRequest** call, the SAN service provider also passes the socket descriptor that was acquired from the switch in a call to the

WPUCreateSocketHandle function. The switch receives completion notifications, matches them to an application's I/O requests, and completes those I/O requests, as appropriate, for the application.

Synchronizing Operations on a SAN

Article • 12/15/2021

The Windows Sockets switch uses its session protocol to handle almost all synchronization between a SAN service provider and applications. That is, the switch, in conjunction with the TCP/IP provider, handles most **WSPAsyncSelect**, **WSPEventSelect**, and **WSPSelect** calls from applications. The switch does not forward these calls to a SAN service provider except when specifying the FD_ACCEPT and FD_CONNECT network event codes in calls to a SAN service provider's **WSPEventSelect** function, as described in Setting Up a SAN Connection.

Shutting Down the Use of a SAN

Article • 12/15/2021

The following topics describe how to terminate the use of a SAN:

Shutting Down a SAN Connection

Closing a SAN Socket

Cleaning up a Process for a SAN

Shutting Down a SAN Connection

Article • 12/15/2021

The Windows Sockets switch uses its session protocol to shut down a connection to a SAN socket. That is, the switch handles **WSPRecvDisconnect**, **WSPSendDisconnect**, and **WSPShutdown** calls from applications. The switch does not forward these calls to a SAN service provider. The switch uses its session protocol to disable the reception and transmission of data on a SAN socket.

Closing a SAN Socket

Article • 12/06/2022

After the Windows Sockets switch on either side of a connection calls a SAN service provider's WSPCloseSocket function, the SAN service provider performs the following procedure to close a SAN socket:

1. Each SAN service provider on either side of the connection tears down the connection and completes receive requests-- WSPRecv function calls--by returning the appropriate error code at the *lpErrno* parameter. For example, a SAN service provider returns WSAECONNRESET to indicate that the remote peer reset the connection.

   Each SAN service provider also signals completion of pending overlapped operations for the SAN socket to be closed. The SAN service provider calls the WPUCompleteOverlappedRequest function to signal completion of an overlapped operation. In this call, the SAN service provider passes a pointer to the WSAOVERLAPPED structure that is associated with the overlapped operation. The SAN service provider also passes the WSA_OPERATION_ABORTED error code to specify that the overlapped operation was canceled because the SAN socket was closed. Before signaling completion of an overlapped operation, the SAN service provider should release any memory that was required for the operation.

2. After the SAN service provider is done making up-calls--calls to functions that are prefixed with **WPU**--to the switch using the handle to the SAN socket that was obtained through a WPUCreateSocketHandle up-call, the SAN service provider must make a final up-call to the switch by calling the WPUCloseSocketHandle function to close the socket handle. The SAN service provider then cleans up everything related to the SAN socket. Up-calls are function calls from the switch's up-call dispatch table. The switch provides a pointer to this up-call dispatch table when it calls the SAN service provider's WSPStartupEx function to start using the provider.

As long as a SAN service provider performs the preceding procedure to close a SAN socket, the switch takes care of everything else.

To prevent race conditions between a SAN service provider and the switch initiating socket closures, the SAN service provider should never release data structures related to a SAN socket until the switch calls **WSPCloseSocket**.

Cleaning up a Process for a SAN

Article • 12/15/2021

When an application is ready to clean up the process in which it is running, it initiates a call to the Windows Sockets switch's **WSPCleanup** function. The switch, in turn, calls the **WSPCleanup** function of the TCP/IP provider and all SAN service providers. All providers are expected to release any resources that they were using. Resources can include, for example, objects used to synchronize events and memory used to perform data transfers.

Blocking Calls for a SAN

Article • 12/15/2021

The Windows Sockets switch handles blocking calls and the cancellation of such calls internally or forwards them to the TCP/IP service provider. The switch never calls a **WSPCancelBlockingCall** function for a SAN service provider to cancel a blocking request that is in progress. Therefore, a SAN service provider is not required to implement a **WSPCancelBlockingCall** function.

The switch handles the following blocking requests and corresponding cancellations in the following ways:

- When an application requests to connect a SAN socket to a specific destination address in blocking mode, the switch receives a blocking **WSPConnect** call. The switch forwards the connect request in nonblocking mode to the appropriate SAN service provider's WSPConnect function. If the switch must cancel this connection request for some reason, it calls the SAN service provider's WSPCloseSocket function. The SAN service provider must promptly abort the connection request and release resources for the socket.

- When the switch receives a blocking request that was initiated by an application to perform a data transfer operation on a SAN socket, it forwards the data transfer request in an overlapped (nonblocking) manner to the appropriate SAN service provider. For example, if the switch receives a synchronous (blocking) **WSPSend** call, it calls the appropriate SAN service provider's WSPSend function in an overlapped (nonblocking) manner. If the application later cancels the data transfer operation and the switch has control of the application's buffer, the switch completes the application's request with a failure status. If the application's buffer is involved in an outstanding RDMA operation, the switch waits for the operation to complete. If an RDMA transfer takes too long to complete, the switch calls the appropriate SAN service provider's **WSPCloseSocket** function to close the connection in an abortive manner, thereby forcing completion.

Note If an application cancels a blocking call, it cannot rely on a connection being preserved. Only the **WSPCloseSocket** call is guaranteed to succeed on the socket after the cancellation of a blocking request. For more information, see the Windows Sockets SPI documentation in the Microsoft Windows SDK.

Duplicating Socket Handles for a SAN

Article • 12/15/2021

Multiple applications that run in different processes can use the Windows Sockets switch to perform operations on a shared underlying socket. However, only one application at a time can perform operations on that shared underlying socket.

To use a shared underlying socket, an application must retrieve a duplicate handle to that underlying socket in one of the following ways:

- Directly, by calling the Windows Sockets **WSADuplicateSocket** function

  The call is made in the context of the controlling process (the process in which the socket was created).

- Indirectly, by calling the Win32 DuplicateHandle function

  The call is made in the context of a noncontrolling process (other than the process in which the socket was created).

- Using the handle inheritance mechanism

  A child process (the noncontrolling process) inherits all or some of the handles created in its parent process (the controlling process).

- During graceful connection closure

  If an application in the controlling process closes a socket and exits while some data still remains to be sent, this remaining data is buffered in the Windows Sockets DLL. Another application in the context of the system service process (the noncontrolling process) subsequently sends this data.

The Windows Sockets switch, in conjunction with the TCP/IP provider, detects and handles each of the preceding conditions. The switch allows only one process at a time to execute operations that either transfer data or change state for an underlying shared socket. Processes dynamically swap control of the underlying socket, as required, to execute requested operations. The switch serializes operations that different processes request to perform on a shared socket and executes those operations in first-in-first-out (FIFO) order. The switch waits for all in-progress operations to complete before swapping control of an underlying socket to another process. Logically, the switch takes control of the underlying socket away from the controlling process as soon as a noncontrolling process requests a qualifying operation. After control is taken away, the switch treats the original controlling process like a noncontrolling process if the original controlling process requests qualifying operations. Note that the switch takes no action on a duplicate socket handle until the noncontrolling process actually uses the duplicate socket handle for a data transfer or state-change operation.

Both the switch and the appropriate SAN service provider are loaded into all processes that share access to a particular underlying socket. The switch maintains its own socket context and connection state information in all processes that share the socket. The SAN service provider is required to maintain its socket context and connection state information only in the process that has control of the underlying socket at any given point in time. The SAN service provider must swap control of its context and connection state information from the current controlling process to the next controlling process whenever the switch requires the swap as described in the following sequence. To minimize the amount of resources that are required for swapping, a SAN service provider can maintain its context and connection state information in all processes that share an underlying socket.

Because the switch does not create the SAN socket that corresponds to an application socket until an application calls either the **connect** or **listen** function, the switch cannot request that the SAN service provider perform a swap operation before the application socket is connected or listening. Even after the application socket is connected or listening, one of the following conditions must be met before the switch requests that the SAN service provider swap control of the socket:

- A process that does not control the socket initiates a data transfer. The SAN service provider does not swap control of the socket until all data transfer operations that were initiated by the controlling process have completed.

- A process that does not control the socket calls the **WSAAccept**, **WSPAccept**, or **AcceptEx** function to start a connection-acceptance operation on a listening socket. The SAN service provider does not swap control of the socket until all accept requests that were initiated by the controlling process have completed.

The switch performs the following steps to swap control of a connected SAN socket from the controlling process to the next-controlling process (For an overview of the swapping process, see the table in the Remarks section of the documentation for the WSPDuplicateSocket function.):

1. The switch suspends processing of new requests from the application in the controlling process. When all send and RDMA operations in progress on the SAN socket have completed, the switch calls the SAN service provider's WSPSend function to send a message to a connected peer to request a suspension of the session and calls the SAN service provider's WSPDeregisterMemory function to release all local buffers used for send operations. As a result, the switch at the peer

connection suspends processing of new application requests, waits for all send and RDMA operations in progress on the SAN socket to complete, and releases all RDMA memory. The peer connection next sends a reply message indicating that the session is suspended. On receiving this confirmation message, the switch at the local endpoint calls the SAN service provider's **WSPDeregisterRdmaMemory** function to release all RDMA memory. At this point, SAN sockets at both endpoints of the connection can only have receive requests pending. These receive requests remain pending on the remote peer's SAN socket to permit reactivation of the session. The receive requests on the local SAN socket in the controlling process are completed in the next step. While the connection is suspended, the switch at the remote peer connection queues new blocking or overlapped requests, buffers new nonblocking sends up to the SO_SNDBUF setting, fails new nonblocking sends after the buffer limit is reached, and fails all new nonblocking receives with WSAEWOULDBLOCK. The local switch in the controlling process handles new requests on the application socket as if the process did not have control of the socket.

2. After the session is suspended, the switch calls the SAN service provider's **WSPDuplicateSocket** function in the controlling process to direct the SAN service provider to transfer the socket context into the address space of the next-controlling process. The switch specifies the next-controlling process in the *dwProcessId* parameter of **WSPDuplicateSocket**. The **WSPDuplicateSocket** function must call the **WPUCompleteOverlappedRequest** function to complete all outstanding receive requests on the socket with a success status and zero bytes. The SAN service provider must also automatically release all buffers associated with these requests. The SAN service provider releases all buffers since the switch does not request any more operations on the SAN socket after **WSPDuplicateSocket** returns. The only possible exception is a **WSPCloseSocket** function call, as described in the next step. After **WSPDuplicateSocket** returns, the switch saves the value in the **dwProviderReserved** member of the WSAPROTOCOL_INFOW structure to which the *lpProtocolInfo* output parameter points. The switch uses this value to identify the underlying socket in the context of the next-controlling process. Therefore, the value in **dwProviderReserved** must uniquely identify the underlying socket and the connection for that socket across all processes on the system. In addition, this value must be valid only in the context of the process that the switch specified in the *dwProcessId* parameter of **WSPDuplicateSocket**.

3. After the socket context is transferred into the address space of the next-controlling process, the switch calls the SAN service provider's WSPSocket function in the context of the next-controlling process. In this call, the switch passes the

value for the underlying socket that was returned in the **WSPDuplicateSocket** call to the **dwProviderReserved** member of the WSAPROTOCOL_INFOW structure to which the *lpProtocolInfo* input parameter points. If the next-controlling process did not request the creation of the SAN socket, the SAN service provider must create a new socket and call the **WPUCreateSocketHandle** function to obtain a handle, as required for any new socket. If the SAN socket was created in the context of the next-controlling process, the SAN service provider can reactivate the former socket and return the same descriptor for the socket that was used previously. In this case, the SAN service provider should not call **WPUCreateSocketHandle**, but should continue to use the original socket handle that the switch provided. Alternatively, the SAN service provider can create a new socket, regardless of whether a socket previously existed in the process. In this case, the switch must call the SAN service provider's WSPCloseSocket function in the context of the next-controlling process to dispose of the former socket descriptor.

4. The switch restarts processing of new requests from the application in the next-controlling process.

The switch duplicates a listening socket in a similar manner, except that the switch is not required to suspend a session. The switch waits until it completes all **WSPAccept** calls that were initiated by an application's **accept** and **AcceptEx** calls before calling the SAN service provider's **WSPDuplicateSocket** function in the controlling process.

Because the switch suspends processing of new requests on a SAN socket prior to calling the SAN service provider's **WSPDuplicateSocket** function, the SAN service provider can release all resources associated with a local endpoint in the controlling process. The SAN service provider can even terminate an underlying connection. If the SAN service provider closes an underlying connection in the controlling process, the SAN service provider must reestablish the connection after the switch calls the SAN service provider's **WSPSocket** function within the next-controlling process. After the **WSPSocket** call returns, the SAN socket within the next-controlling process must be in the same state, from the switch's perspective, as the SAN socket in the controlling process was prior to the switch calling the SAN service provider's **WSPDuplicateSocket** function.

If a SAN NIC supports sharing resources between endpoints that run in different processes, the SAN service provider does not have to release resources for a local endpoint in the controlling process prior to receiving a **WSPDuplicateSocket** call. In such a case, the SAN socket associated with a local endpoint remains inactive in the former-controlling process until the switch either swaps the socket context back from the next-controlling process or calls the SAN service provider's **WSPCloseSocket** function to explicitly close the socket. Because most applications perform their final access to the socket in the process that originally created it--generally to close the connection--the SAN service provider can improve performance if the SAN service provider preserves the socket context in the controlling process after the switch swaps control of the socket to the next-controlling process.

Note that, in all cases, a SAN socket descriptor must remain valid until the switch calls the SAN service provider's **WSPCloseSocket** function to explicitly close the socket. Even if the SAN service provider releases all resources for the socket in a particular process prior to receiving a **WSPDuplicateSocket** call, the SAN service provider must not reuse the descriptor for the socket until the switch calls **WSPCloseSocket** on that descriptor.

An unexpected process exit or some other error condition can interrupt a SAN service provider's socket-duplication operation. For example, a shortage of resources can cause such an interruption. The switch treats such error conditions as it does any other error situation. If necessary, the switch closes all descriptors that are associated with the underlying socket in all processes to forcefully terminate the socket's connection. If at all possible, the SAN service provider at the remote peer should complete **WSPRecv** calls that receive incoming data with an appropriate error code, such as WSAECONNRESET. This error code informs the remote peer of the connection termination. If the switch at the remote peer does not receive this connection-termination indication, the switch at the remote peer times out a suspended connection if the system that requested the suspension fails.

Handling Socket Options and Control Codes for a SAN

Article • 12/15/2021

The Windows Sockets switch, in conjunction with the TCP/IP provider, handles most **WSPGetSockOpt**, **WSPSetSockOpt**, and **WSPIoctl** calls initiated by applications. These requests are generally to set and retrieve options and operating parameters associated with an application's socket. The switch does not generally forward these calls to a SAN service provider except as described in the following sections.

Retrieving SAN socket options

The Windows Sockets switch calls a SAN service provider's WSPGetSockOpt function and passes one of the following socket options to retrieve the current value of that option, if the SAN service provider supports that option:

SO_DEBUG
SAN service providers are not required to support this option. They are encouraged, but not required, to supply output debug information if applications set the SO_DEBUG option.

SO_MAX_MSG_SIZE
A SAN service provider must support this option if the underlying SAN transport is message-oriented and the transport limits the amount of data that the switch can send in a call to the SAN service provider's WSPSend function. The switch does not subsequently pass send requests to the SAN service provider that exceed the size that the SAN service provider returns for the value of this option.

SO_MAX_RDMA_SIZE
A SAN service provider must support this option if the underlying SAN transport limits the amount of data that the switch can transfer in calls to either the SAN service provider's WSPRdmaRead or WSPRdmaWrite function. The switch does not subsequently pass RDMA transfer requests to the SAN service provider that exceed the size that the SAN service provider returns for the value of this option.

SO_RDMA_THRESHOLD_SIZE
A SAN service provider supports this option to indicate its preference for the minimum amount of data that the switch can transfer in calls to either the SAN service provider's **WSPRdmaRead** or **WSPRdmaWrite** function. However, the switch can set the actual threshold to a value different from the value returned by the SAN service provider. The

switch subsequently calls the **WSPRdmaRead** or **WSPRdmaWrite** function to transfer data blocks (RDMA transfers) that exceed the size of this threshold and the **WSPSend** or **WSPRecv** function to transfer data blocks (message-oriented transfers) that are less than or equal to the size of this threshold.

SO_GROUP_ID, SO_GROUP_PRIORITY
A SAN service provider must support these options if it supports quality of service (QoS). Otherwise, the switch forwards these options to the TCP/IP provider, which maintains default values. A SAN service provider indicates that it supports QoS by setting the XP1_QOS_SUPPORTED bit in the **dwServiceFlags** member of the WSAPROTOCOL_INFO structure.

Setting SAN socket options

The Windows Sockets switch calls a SAN service provider's **WSPSetSockOpt** function and passes one of the following socket options to set a value for that option, if the SAN service provider supports that option:

SO_DEBUG
For a description of this socket option, see the preceding list.

SO_GROUP_PRIORITY
For a description of this socket option, see the preceding list.

Accessing SAN socket information

The Windows Sockets switch calls a SAN service provider's **WSPIoctl** function and passes one of the following control codes to set or retrieve information for that SAN service provider, if the SAN service provider supports that control code:

SIO_GET_EXTENSION_FUNCTION_POINTER
Retrieves a pointer to an extension function that a SAN service provider must support. For more information about extension functions, see Windows Sockets SPI Extensions for SANs. The input buffer of the **WSPIoctl** call contains the GUID whose value identifies the specified extension function. The SAN service provider returns the pointer to the requested function in **WSPIoctl**'s output buffer. The following table contains GUIDs for extension functions that a SAN service provider can support:

Extension function	GUID
WSPRegisterMemory	{C0B422F5-F58C-11d1-AD6C-00C04FA34A2D}
WSPDeregisterMemory	{C0B422F6-F58C-11d1-AD6C-00C04FA34A2D}

Extension function	GUID
WSPRegisterRdmaMemory	{C0B422F7-F58C-11d1-AD6C-00C04FA34A2D}
WSPDeregisterRdmaMemory	{C0B422F8-F58C-11d1-AD6C-00C04FA34A2D}
WSPRdmaWrite	{C0B422F9-F58C-11d1-AD6C-00C04FA34A2D}
WSPRdmaRead	{C0B422FA-F58C-11d1-AD6C-00C04FA34A2D}
WSPMemoryRegistrationCacheCallback	{E5DA4AF8-D824-48CD-A799-6337A98ED2AF}

SIO_GET_QOS, SIO_GET_GROUP_QOS, SIO_SET_QOS, SIO_SET_GROUP_QOS
A SAN service provider must support these control codes if it supports QoS. Otherwise, the switch forwards these options to the TCP/IP provider, which maintains default values. A provider indicates that it supports QoS by setting the XP1_QOS_SUPPORTED bit in the **dwServiceFlags** member of the WSAPROTOCOL_INFO structure.

SIO_ADDRESS_LIST_QUERY
Retrieves the list of local IP addresses that are assigned to the network interface cards (NICs) that the SAN service provider controls. The SAN service provider uses a SOCKET_ADDRESS_LIST structure, defined as follows, to return the list in **WSPIoctl**'s output buffer:

C++

```
typedef struct _SOCKET_ADDRESS_LIST {
    INT             iAddressCount;
    SOCKET_ADDRESS  Address[1];
} SOCKET_ADDRESS_LIST, FAR * LPSOCKET_ADDRESS_LIST;
```

The members of this structure contain the following information:

iAddressCount
Specifies the number of address structures in the list.

Address
Array of IP address structures.

The switch uses this IOCTL code internally to decide whether to use a given SAN service provider to execute an application's requests to make connections or to listen for incoming connections. The switch forwards actual application requests for the list of local IP addresses to the TCP/IP provider. The switch also uses the TCP/IP provider to detect changes in address lists that all SAN service providers service. After TCP/IP reports a change, the switch queries all SAN service providers to refresh their lists.

Handling Microsoft Extensions to Windows Sockets

Article • 12/15/2021

The Windows Sockets switch handles all Microsoft-specific Windows Sockets extension functions internally. The Windows Sockets documentation in the Microsoft Windows SDK defines an extension as a mechanism that exposes advanced transport functionality to application programs. These extension functions are: **TransmitFile**, **AcceptEx**, and **GetAcceptExSockAddrs**. The switch converts these calls, as necessary, and forwards them to the appropriate SAN service provider function: **WSPSend**, **WSPAccept**, **WSPRdmaWrite**, or **WSPRdmaRead**.

Creating a Service Provider for a SAN

Article • 12/15/2021

This section provides a brief description of the functions that make up the interface between a SAN service provider DLL and the Windows Sockets switch. The SAN service provider DLL exports a single entry point for its initialization function **WSPStartupEx**. The SAN service provider's **WSPStartupEx** function in turn makes most of the other interface functions accessible to the Windows Sockets switch through a dispatch table. The remaining interface functions are supplied to the switch through calls to the SAN service provider's **WSPIoctl** function. The interface functions include Windows Sockets SPI functions and SAN-specific extensions to the Windows Sockets SPI interface.

The Windows Sockets Direct reference provides detailed information about these functions as implemented in a SAN service provider. Do not use the Microsoft Windows SDK descriptions of the Windows Sockets SPI functions. The Windows SDK descriptions do not contain SAN-specific requirements.

This section also lists the Windows Sockets SPI functions that a SAN service provider is not required to supply.

Windows Sockets SPI Functions Required for SANs

Article • 12/15/2021

This section describes the functions of the Windows Sockets SPI that a SAN service provider DLL must supply. These functions are defined in Ws2spi.h and are fully documented in the Windows Sockets Direct Reference section:

WSPAccept
Conditionally accepts a connection for a socket that is listening for connections, based on the return value of a supplied condition function.

WSPBind
Associates the local IP address, or name, of a network interface with a socket. This network interface is serviced by the SAN service provider.

WSPCleanup
Terminates use of the SAN service provider DLL.

WSPCloseSocket
Closes a socket.

WSPConnect
Establishes the connection of a socket to a peer, exchanges connect data, and specifies required quality of service (QoS) based on the supplied flow specification.

WSPDuplicateSocket
Retrieves a WSAPROTOCOL_INFOW structure that can be used to create a new socket descriptor for a shared socket in the context of another process.

WSPEnumNetworkEvents
Reports occurrences of network events for a socket.

WSPEventSelect
Specifies an event object for a socket. This event object is subsequently set by the occurrence of the supplied set of network events.

WSPGetOverlappedResult
Returns the results of an asynchronous (overlapped) operation on a socket. This operation previously indicated that it was pending completion.

WSPGetQOSByName
Initializes a QoS structure based on a named template, or retrieves an enumeration of

the available template names.

A SAN service provider DLL that supports QoS must fully implement **WSPGetQOSByName**. If the SAN service provides does not support QoS, its **WSPGetQOSByName** function must at least return the error WSAEOPNOTSUPP.

WSPGetSockOpt
Retrieves the current value of an option for a socket.

WSPIoctl
Sets or retrieves operating parameters associated with a socket.

WSPListen
Establishes a socket to listen for incoming connections.

WSPRecv
Receives data on a connected socket.

WSPSend
Sends data on a connected socket.

WSPSetSockOpt
Sets the value of an option for a socket.

WSPSocket
Creates a socket that uses the TCP/IP protocol and asynchronous (overlapped) data transfer.

Windows Sockets SPI Functions not Required for SANs

Article • 12/15/2021

This section describes the functions of the Windows Sockets SPI that a SAN service provider is not required to implement. These functions are defined in Ws2spi.h.

WSPAddressToString
The Windows Sockets switch uses the TCP/IP provider to convert all components of a SOCKADDR structure into a human-readable numeric string that represents the IP address of a socket.

WSPAsyncSelect
The Windows Sockets switch uses its session protocol internally to handle notification of network events for a socket, if necessary.

WSPCancelBlockingCall
The Windows Sockets switch internally handles the cancellation of blocking requests that are in progress. Therefore, it never issues cancel blocking calls to a SAN service provider DLL. The Windows Sockets switch can either:

Cancel an outstanding connect request by closing the SAN socket. The SAN service provider DLL should abort the connect request.

Cancel outstanding send and receive requests by discarding data for those requests if the switch buffers that data internally, or by waiting for those requests to complete if they are RDMA transfers to or from application buffers. For lengthy RDMA transfers, the switch can close the connection altogether.

The Windows Sockets SPI documentation in the Microsoft Windows SDK warns that if a blocking call is canceled, an application cannot rely on a connection being preserved. In this case, the only call that is guaranteed to succeed on the socket after the cancellation of a blocking request is **WSPCloseSocket**.

WSPGetPeerName The Windows Sockets switch caches the IP address of a peer when the switch establishes a connection to the peer in a **WSPConnect** call or accepts a connection to the peer in a **WSPAccept** call. The switch provides this cached value to applications, if necessary.

WSPGetSockName The Windows Sockets switch caches the local IP address for a socket when the switch associates the address with the socket in a **WSPBind** call or accepts a connection to a peer in a **WSPAccept** call. The switch provides this cached value to applications, if necessary.

WSPJoinLeaf The Windows Sockets switch exclusively uses the TCP/IP provider to handle multipoint sessions.

WSPRecvDisconnect The Windows Sockets switch internally handles termination of data reception on a socket and retrieves any incoming disconnect data from the remote party.

WSPRecvFrom The current version of Windows Sockets Direct does not support SAN service providers handling sockets that receive datagrams with User Datagram Protocol (UDP) semantics. Therefore, the Windows Sockets switch calls a SAN service provider's **WSPRecv** function on a connected socket to receive stream data with Transmission Control Protocol (TCP) semantics.

WSPSelect The Windows Sockets switch uses its session protocol internally in cooperation with the TCP/IP provider to determine the status of sockets, if necessary.

WSPSendDisconnect The Windows Sockets switch internally handles termination of the connection for a socket and sends disconnect data to the remote party.

WSPSendTo The current version of Windows Sockets Direct does not support SAN service providers handling sockets that send datagrams with User Datagram Protocol (UDP) semantics. Therefore, the Windows Sockets switch calls a SAN service provider's **WSPSend** function on a connected socket to send stream data with Transmission Control Protocol (TCP) semantics.

WSPShutdown The Windows Sockets switch internally disables the reception and transmission of data on a socket.

WSPStartup The Windows Sockets switch does not call **WSPStartup** to start the operation of a SAN service provider. The switch instead uses the SAN service provider's **WSPStatupEx** function.

WSPStringToAddress The Windows Sockets switch uses the TCP/IP provider to convert a human-readable numeric string that represents the IP address of a socket into a socket address structure (SOCKADDR) that is suitable to pass to Windows Sockets routines that take such a structure.

Windows Sockets SPI Extensions for SANs

Article • 12/15/2021

This section provides a brief description of the SAN extension functions that a SAN service provider DLL must supply. These functions extend the Windows Sockets SPI for use with a SAN. The extended functions are defined in Ws2san.h and are fully documented in the Windows Sockets Direct Reference section.

Except for the **WSPStartupEx** function, the extended functions listed in this section are retrieved by the Windows Sockets switch. To retrieve the entry point to each of these extended functions, the Windows Sockets switch calls a SAN service provider's **WSPIoctl** function and passes the SIO_GET_EXTENSION_FUNCTION_POINTER command code along with the GUID whose value identifies one of these extended functions.

A SAN service provider must implement all of the following extension functions with the exception of the **WSPRdmaRead** and **WSPMemoryRegistrationCacheCallback** functions. If a SAN service provider does not support either the **WSPRdmaRead** or **WSPMemoryRegistrationCacheCallback** extension function, its **WSPIoctl** function must return the error WSAEOPNOTSUPP when the Windows Sockets switch requests the entry point to either **WSPRdmaRead** or **WSPMemoryRegistrationCacheCallback**.

WSPStartupEx
Initiates the Windows Sockets switch's use of a SAN service provider.

WSPRegisterMemory
Registers a buffer array that a socket uses as either the local source or the local target of a data transfer operation. Such a socket can use this buffer array as the source buffer in **WSPRdmaWrite** and **WSPSend** calls and the receiving buffer in **WSPRdmaRead** and **WSPRecv** calls.

WSPDeregisterMemory
Releases a buffer array that was registered by a previous call to the **WSPRegisterMemory** function.

WSPRegisterRdmaMemory
Registers an RDMA buffer array that is exposed to a remote peer connection for transferring data to or from that peer connection. A socket at the remote peer can use this RDMA buffer array as the target buffer in a **WSPRdmaWrite** call and the source buffer in a **WSPRdmaRead** call.

WSPDeregisterRdmaMemory

Releases a buffer array that was registered by a previous call to the **WSPRegisterRdmaMemory** function.

WSPMemoryRegistrationCacheCallback

Releases ownership of an application's buffer and the lock between the buffer and physical memory and removes the buffer from the SAN service provider's cache and the buffer registration from the SAN NIC.

WSPRdmaRead

Transfers data from an RDMA buffer in the address space that a socket's remote peer can access to a buffer in the address space that the local socket can access.

WSPRdmaWrite

Transfers data from a source buffer in the address space that a local socket can access to a target RDMA buffer in the address space that the socket's remote peer can access.

Creating a Proxy Driver for a SAN Service Provider

Article • 12/15/2021

A proxy driver for a SAN service provider is a kernel-mode driver that performs tasks required by the Windows Sockets switch and the SAN service provider. Such tasks include managing memory and determining the IP addresses of network interface controllers (NICs) that are under the proxy driver's control. The proxy driver is not required to be a Windows Driver Model (WDM) driver. That is, it is not required to support Plug and Play or power management. For more information about developing a kernel-mode driver, see Kernel-Mode Driver Components.

Different vendors might use different underlying technologies to implement their SAN network interface controllers (NICs), therefore Windows Sockets Direct does not specify an interface between a SAN service provider and its proxy driver or between the proxy driver and a SAN transport.

A SAN NIC vendor must implement a transport interface that is suitable for its underlying technologies. A vendor can implement this interface in the SAN NIC, in a kernel-mode driver for the SAN NIC, or both. A SAN service provider maps this interface directly into a user-mode process's address space. A vendor must ensure that all buffers passed across this interface are locked down and registered with the SAN NIC.

The following sections describe how to create a proxy driver for a SAN service provider DLL:

Initializing and Unloading a SAN Proxy Driver

Allocating and Releasing Memory for a SAN Proxy Driver

Securing and Releasing Ownership of Virtual Addresses

Registering for SAN NIC Notifications

Translating to a SAN Native Address

Implementing IOCTLs for a SAN Service Provider

Initializing and Unloading a SAN Proxy Driver

Article • 12/15/2021

In addition to creating and initializing a device object for the driver object, the proxy driver's **DriverEntry** routine can register to be notified when NICs under the driver's control are either added or removed. For more information, see Registering for SAN NIC Notifications.

If the proxy driver's SAN service provider sends I/O control requests down to the proxy driver, then **DriverEntry** must specify an *entry point* that enables device control. The provider might request, for example, to retrieve the list of IP addresses assigned to the driver's NICs. An entry point for this request is an **IRP_MJ_DEVICE_CONTROL** dispatch routine that returns the list of IP addresses assigned to the driver's NICs. For more information, see Implementing IOCTLs for a SAN Service Provider.

The **DriverEntry** routine must specify an entry point for a routine that unloads the proxy driver. This unload routine removes the device that was created in **DriverEntry**.

Allocating and Releasing Memory for a SAN Proxy Driver

Article • 12/15/2021

The proxy driver must set up access to user buffers so that the Windows Sockets switch can transfer control messages and perform RDMA operations. To request this type of buffer access, the proxy driver sets a bit in the **Flags** member of its device object to DO_DIRECT_IO. The proxy driver must also allocate or release memory that is used for message transfer and RDMA whenever requested to do so. When the Windows Sockets switch requests a SAN service provider to register or release memory, the SAN service provider requests its proxy driver to respectively allocate or release physical memory. For more information about setting up buffer access and allocating and releasing memory, see Memory Management and Buffer Management.

Allocating Low Memory for RDMA

A proxy driver must allocate memory that can be accessed for RDMA operations. The proxy driver can allocate low memory for RDMA operations even on an system that is configured so that no physical memory below 4 GB can be allocated. (This is called a NOLOWMEM configuration.) The proxy driver calls either the **MmAllocateContiguousMemorySpecifyCache** function or its own DMA **AllocateCommonBuffer** function to retrieve low memory.

To retrieve a pointer to its DMA **AllocateCommonBuffer** function, the proxy driver performs the following steps:

1. Zero-initializes a **DEVICE_DESCRIPTION** structure and then writes relevant information for its SAN NIC to this structure.

2. Calls **IoGetDmaAdapter** to retrieve a pointer to the DMA adapter structure for its SAN NIC. In this call, the driver passes a pointer to the filled-in DEVICE_DESCRIPTION structure. **IoGetDmaAdapter** returns a pointer to a DMA adapter structure that contains a pointer to a **DMA_OPERATIONS** structure. DMA_OPERATIONS contains pointers to a system-defined set of DMA functions. One of these functions is **AllocateCommonBuffer**, which allocates a physically contiguous DMA buffer.

Securing and Releasing Ownership of Virtual Addresses

Article • 12/15/2021

The proxy driver must secure ownership of the virtual addresses of user-mode buffers whenever the SAN service provider for the proxy driver caches those buffers. For more information about caching buffers, see Caching Registered Memory. The proxy driver secures ownership of a user-mode buffer, so that the operating system notifies the Windows Sockets switch if the buffer is released back to the operating system by an application. To secure ownership of a buffer, the proxy driver must call the **MmSecureVirtualMemory** function. In this call, the proxy driver passes a pointer to the starting address of the buffer and the size, in bytes, of the buffer.

If the virtual-to-physical mappings for the cached buffer are scheduled to change, the switch is notified and calls the SAN service provider's **WSPMemoryRegistrationCacheCallback** function to remove the buffer registration from the SAN NIC and the buffer from the SAN service provider's cache. The SAN service provider's proxy driver, in turn, must call the **MmUnsecureVirtualMemory** function to release ownership of the buffer. In this call, the proxy driver passes the handle to the buffer that was previously returned from the **MmSecureVirtualMemory** call.

Note A driver that tries to access a user-mode buffer that was secured through a call to **MmSecureVirtualMemory** can potentially bring down the operating system. Therefore, when the proxy driver accesses such a user-mode buffer, it must also use the **try/except** mechanism around the code that accesses the buffer. For more information about **try/except**, see the Visual C++ documentation.

A SAN service provider can send I/O control (IOCTL) requests to the proxy driver to secure and release ownership of a buffer. For more information, see Implementing IOCTLs for a SAN Service Provider.

Registering for SAN NIC Notifications

Article • 12/15/2021

When a proxy driver receives a request from its associated SAN service provider to supply the list of IP addresses assigned to NICs under the driver's control, the driver determines and passes this list to the provider.

In order to obtain these IP addresses, the proxy driver must register with the Transport Driver Interface (TDI) to receive address change notifications. The proxy driver calls the TdiRegisterPnPHandlers function. In this call, this proxy driver passes pointers to callback functions in the **AddAddressHandlerV2** and **DelAddressHandlerV2** members of the TDI_CLIENT_INTERFACE_INFO structure to specify callback functions for address additions and deletions. After the **TdiRegisterPnPHandlers** function has returned successfully, TDI immediately indicates all currently active network addresses to the proxy driver, using the address-addition callback. The indication contains both network addresses and identifiers for the devices to which those addresses are bound.

Whenever TDI calls either of these callback functions to indicate address additions or deletions, the proxy driver requires the following parameters:

Address
Pointer to a TA_ADDRESS structure that describes the network address either assigned to or removed from the NIC. In the case of TCP/IP, this pointer is actually be a pointer to a TA_ADDRESS_IP structure.

DeviceName
Pointer to a Unicode string that identifies the transport-to-NIC binding with which the address is associated. In case of TCP/IP, the Unicode string has the following format: \Device\Tcpip_{NIC-GUID}, where NIC-GUID is the globally unique identifier assigned by the network configuration subsystem to the NIC.

The preceding structure definitions are defined in the tdi.h header file. The preceding registration and callback functions are defined in the tdikrnl.h header file. These header files are available in the Microsoft Windows Driver Development Kit (DDK) and the Windows Driver Kit (WDK). For detailed information about TDI Plug and Play (PnP) notifications, see TDI Client Callbacks and TDI Client Event and PnP Notification Handlers.

At system startup, TDI calls the proxy driver's address-addition callback to indicate all currently active IP addresses. TDI also calls this callback whenever the TCP/IP transport protocol registers a new IP address with TDI. The proxy driver includes in its list of IP addresses only those addresses assigned to the proxy driver's NICs. The driver's address-addition callback should return control promptly if the driver does not recognize the NIC at *DeviceName*.

TDI calls the proxy driver's address-removal callback whenever the TCP/IP transport protocol indicates to TDI that a NIC has been removed. If the IP address of the NIC belongs to one of the proxy driver's NICs, the proxy driver removes the IP address from the list.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Translating to a SAN Native Address

Article • 12/15/2021

The Windows Sockets switch always uses the WSK address families to interact with a SAN service provider, not the SAN's native address family. Therefore, a proxy driver for a SAN service provider must translate between WSK address families and native addresses accordingly.

A proxy driver uses TDI Plug and Play (PnP) notifications to maintain the list of IP addresses assigned to each NIC under its control, as described in Registering for SAN NIC Notifications. The proxy driver uses this list to translate between native SAN addresses and IP addresses.

The proxy driver receives requests from its SAN service provider that contain IP addresses. These requests include, for example, the request to bind to a specific NIC and the request to connect to a remote peer. The proxy driver must translate to native SAN addresses to complete these requests. The proxy driver also receives incoming connection requests from remote peers that contain SAN native addresses of those remote peers. The proxy driver must translate to the IP addresses of those remote peers to complete these requests.

Note TDI will not be supported in Microsoft Windows versions after Windows Vista. Use Windows Filtering Platform or Winsock Kernel instead.

Implementing IOCTLs for a SAN Service Provider

Article • 12/15/2021

If a SAN service provider sends I/O control (IOCTL) requests to the proxy driver, the driver should implement an IRP_MJ_DEVICE_CONTROL dispatch routine to process these requests. An IOCTL request can be a request to retrieve the list of IP addresses assigned to the driver's NICs, for example, or a request to allocate or release memory. The **DriverEntry** routine must specify an entry point for the dispatch routine.

The proxy driver's device control routine calls the IoGetCurrentIrpStackLocation function, in which the device control routine passes a pointer to the IRP that was passed to the routine. The device control routine then determines which IOCTL request was received and processes the request accordingly.

After the current IOCTL request completes, the device control routine calls the IoCompleteRequest function and passes the status of the operation. This status is returned to the SAN service provider.

Introduction to Remote NDIS (RNDIS)

Article • 09/27/2024

Remote NDIS (RNDIS) is a bus-independent class specification for Ethernet (802.3) network devices on dynamic Plug and Play (PnP) buses such as USB, 1394, Bluetooth, and InfiniBand. Remote NDIS defines a bus-independent message protocol between a host computer and a Remote NDIS device over abstract control and data channels. Remote NDIS is precise enough to allow vendor-independent class driver support for Remote NDIS devices on the host computer.

Microsoft Windows versions beginning with Windows XP include a Remote NDIS driver for USB devices. This NDIS miniport driver, Rndismp.sys, is implemented and maintained by Microsoft and is distributed as part of all supported Windows versions. You can find it in the %SystemRoot%\System32\drivers directory.

To use this driver with a USB device, an IHV must provide an INF file that follows the template in Remote NDIS INF Template.

Remote NDIS messages are sent to a Remote NDIS device from the host, and a Remote NDIS device responds with an appropriate completion message. Messages are also sent in an unsolicited fashion from a Remote NDIS device to the host.

This section includes:

Overview of Remote NDIS (RNDIS)

Remote NDIS Communication

Remote NDIS To USB Mapping

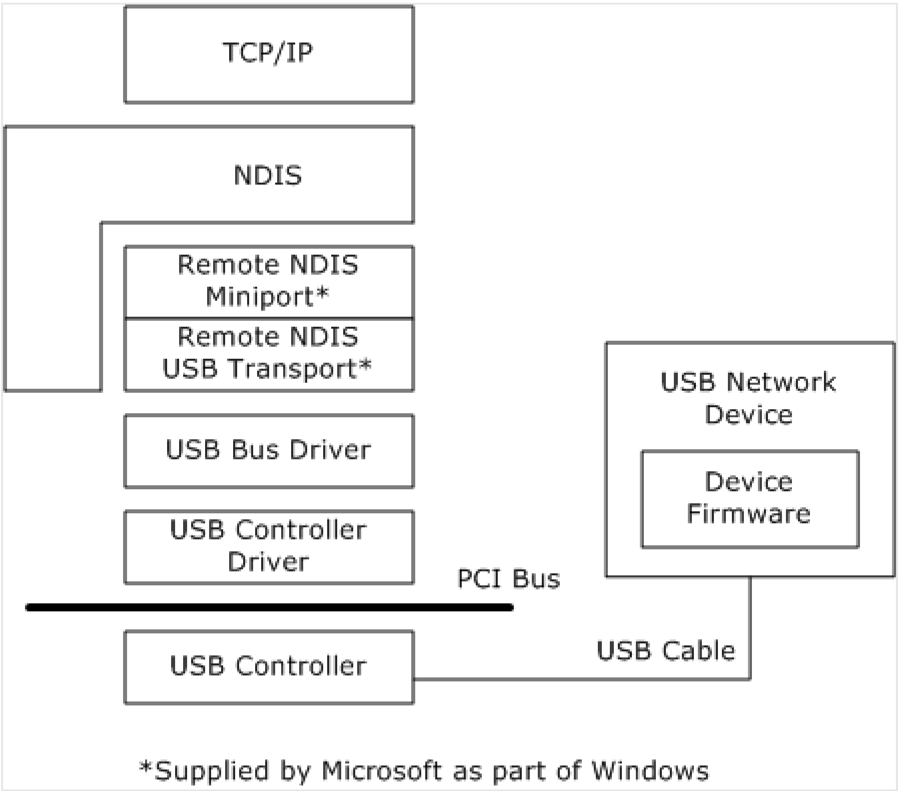
Overview of Remote NDIS (RNDIS)

Article • 09/27/2024

Remote NDIS (RNDIS) eliminates the need for hardware vendors to write an NDIS miniport device driver for a network device attached to the USB bus. Remote NDIS accomplishes this by defining a bus-independent message set and a description of how this message set operates over the USB bus. Because this Remote NDIS interface is standardized, one set of host drivers can support any number of networking devices attached to the USB bus. This significantly reduces the development burden on device manufacturers, improves the overall stability of the system because no new drivers are required, and improves the end-user experience because there are no drivers to install to support a new USB bus-connected network device. Currently Microsoft Windows provides support for Remote NDIS over USB.

The following figure shows the replacement of the device manufacturer's NDIS miniport with the combination of a Remote NDIS miniport driver and a USB transport driver. The device manufacturer can therefore concentrate on device implementation and not have to develop a Windows NDIS device driver.



Microsoft provides an NDIS miniport driver, Rndismp.sys, which implements the Remote NDIS message set and communicates with generic bus transport drivers, which in turn communicate with the appropriate bus driver. This NDIS miniport driver is implemented and maintained by Microsoft and is distributed as part of Windows.

The following Remote NDIS message set mirrors the semantics of the NDIS miniport driver interface:

- Initializing, resetting, and halting device operation
- Transmitting and receiving networking data packets
- Setting and querying device operational parameters
- Indicating media link status and monitoring device status

Microsoft also provides a USB bus transport driver that implements a mechanism for carrying the Remote NDIS messages across the USB bus. This driver transports standardized Remote NDIS messages between the Remote NDIS miniport driver and the bus-specific driver, such as USB. The bus-specific drivers are also required to map any bus-specific requirements, such as power management, into standardized Remote NDIS messages. The transport driver for USB 1.1 and 2.0 is implemented and maintained by Microsoft and distributed as part of Windows.

This structure allows a single device driver to be used for any Remote NDIS device for which there's a bus-specific transport layer. In addition, only one bus transport layer is required for all network devices on a specific bus.

Benefits of Remote NDIS

Article • 03/14/2023

Remote NDIS is an extension of the well-understood and time-tested NDIS architecture. NDIS defines a function-call interface for device-specific NDIS miniport drivers. This interface defines primitives to send and receive network data, and to query and set configuration parameters and statistics. Remote NDIS leverages NDIS by defining a message wrapping for the NDIS miniport driver interface, thus moving the NDIS-handling code from a miniport driver into the device itself. In this and other ways, Remote NDIS allows for a wide range of device functionality and performance levels. The Remote NDIS model has many advantages:

- Extensibility without change to the bus-specific message transport mechanisms
- Ability to support more protocols over more buses in a short time
- Driver architecture that has been proven for both networking and external bus device models

Value-added mechanisms that already exist in the NDIS network stack are supported for Remote NDIS devices.

Remote NDIS Concepts and Definitions

Article • 03/14/2023

This section presents an overview of the Remote NDIS requirements on the communication channel and lower-layer drivers that are used to communicate between the host and the Remote NDIS device. Device state transitions and major operations such as initialization, halt and reset are also described in this section.

- **Control Channel**

  The control channel must be reliable and ensure sequenced delivery. It is used for all communication except for the transmission of network data packets. All required control messages, except REMOTE_NDIS_HALT_MSG and REMOTE_NDIS_INDICATE_STATUS_MSG, are request and response exchanges initiated by the host. The device must respond within the time-out period as specified for each bus.

- **Data Channel**

  The data channel is used exclusively for the transmission of network data packets. It may consist of multiple subchannels (for example, for varying quality of service) as defined for the appropriate bus.

- **Initialization and Teardown**

  The control and data channels are initialized and set up as specified for the appropriate bus. The host sends a REMOTE_NDIS_INITIALIZE_MSG message to the Remote NDIS device. The Remote NDIS device provides information about its type (connectionless or connection-oriented), supported medium, and version in the response message REMOTE_NDIS_INITIALIZE_CMPLT.

  Either the host or the Remote NDIS device can tear down the communication channel through the REMOTE_NDIS_HALT_MSG message. All outstanding requests and packets are discarded on receipt of this message.

- **Device State Definitions**

  Following bus-level initialization, the device is said to be in the RNDIS-uninitialized state. Upon receiving a REMOTE_NDIS_INITIALIZE_MSG and responding with a REMOTE_NDIS_INITIALIZE_CMPLT with a status of RNDIS_STATUS_SUCCESS, the device enters the RNDIS-initialized state.

Upon receiving REMOTE_NDIS_SET_MSG specifying a nonzero filter value for OID_GEN_CURRENT_PACKET_FILTER, the device enters the RNDIS-data-initialized state.

When in the state RNDIS-data-initialized, reception of a REMOTE_NDIS_SET_MSG specifying a zero filter value for OID_GEN_CURRENT_PACKET_FILTER forces the device back to the RNDIS-initialized state.

Reception of REMOTE_NDIS_HALT_MSG or a bus-level disconnect or hard-reset at any time forces the device to the RNDIS-uninitialized state.

- **Halt**

  At any time that the device is in the RNDIS-initialized or RNDIS-data-initialized state, the host computer may terminate the Remote NDIS functionality of the device by sending REMOTE_NDIS_HALT_MSG to the device.

- **Resetting the Communication Channel**

  The communication channel is reset when an error, such as message time-out, occurs. The host may initiate a reset at any time when the device is in the RNDIS-initialized state by sending the message REMOTE_NDIS_RESET_MSG to the device and the device must send a response message when it has completed the reset. For example, the host may initiate a reset when an error, such as a message time-out, has occurred.

  Note that this is a soft reset in the sense that any handles (for example, VCs for connection-oriented devices) continue to be valid after the reset. The Remote NDIS device discards all outstanding requests and packets as part of the reset process. The remote device might reset some of its hardware components, but keeps the communication channel intact.

  If the Remote NDIS device performs a reboot, this event is equivalent to "Remove" followed by "Add" Plug and Play events. The host NDIS miniport driver will be halted and removed, and a new instance will be added and started. All bus-level and Remote NDIS initialization will be re-executed. A Remote NDIS device may reboot itself in the event of a critical device failure.

- **Flow Control**

  The Remote NDIS device may need to exercise flow control to prevent the host from overflowing its data buffers with packets. Any flow control provisions or requirements are bus specific.

- **Numeric Byte Ordering**

All numeric values in Remote NDIS messages must be coded in little-endian format (least significant byte first).

- **NDIS Message Encapsulation**

  There is no Remote NDIS specification for the way NDIS messages are encapsulated in native bus messages or primitives.

Remote NDIS File Naming Conventions

Article • 03/14/2023

In order to support legacy Remote NDIS devices, multiple Remote NDIS drivers have been included with various versions of Windows. The following table lists the Remote NDIS driver names used in each version of Windows.

Remote NDIS file name	Windows version in which this driver is available
Rndismp.sys Usb8023.sys	These binaries are shipped only for legacy device support. No Remote NDIS device INF file should reference these drivers.
Rndismpy.sys Usb8023y.sys	Windows 2000. Were provided separately from the operating system. These are the only binaries for which Microsoft grants redistribution rights.
Rndismpx.sys Usb8023x.sys Netrndis.inf	• Windows XP SP2 and later • Windows XP x64 • Windows Server 2003 SP1 (x86, x64, ia64) and later • Windows Vista (x86, x64) and later The Rndismpx.sys and Usb8023x.sys binaries ship as part of the operating system. The Netrndis.inf file is an internal file that is part of the operating system. All these files must be referenced by the IHV-provided INF file as described in Remote NDIS INF Template.

Note Remote NDIS is not supported on Windows 98/Me/SE or prior versions.

Remote NDIS Messaging

Article • 03/14/2023

There are two types of Remote NDIS messages: *control messages* and *data messages*. Control messages allow the host and Remote NDIS device to communicate with each other over the communication channel. Data messages contain the message data information needed for the communication between the host and device and are communicated over the data channel.

- **Remote NDIS Control Messages**

  Remote NDIS control messages can be sent by the host to the Remote NDIS device and by the Remote NDIS device to the host. The following Remote NDIS control messages must be supported by an Ethernet 802.3 connectionless device:

  REMOTE_NDIS_INITIALIZE_MSG

  REMOTE_NDIS_INITIALIZE_CMPLT

  REMOTE_NDIS_HALT_MSG

  REMOTE_NDIS_QUERY_MSG

  REMOTE_NDIS_QUERY_CMPLT

  REMOTE_NDIS_SET_MSG

  REMOTE_NDIS_SET_CMPLT

  REMOTE_NDIS_RESET_MSG

  REMOTE_NDIS_RESET_CMPLT

  REMOTE_NDIS_INDICATE_STATUS_MSG

  REMOTE_NDIS_KEEPALIVE_MSG

  REMOTE_NDIS_KEEPALIVE_CMPLT

- **Remote NDIS Data Message**

  A Remote NDIS device must send and receive data through Remote NDIS data packets contained in the REMOTE_NDIS_PACKET_MSG message structure. Remote NDIS data packets may also contain out of band data as well as the data that goes across the network.

Both connectionless (for example, 802.3) and connection-oriented (for example, ATM) devices use the same **REMOTE_NDIS_PACKET_MSG** message structure, in order to facilitate common code for packet processing.

Remote NDIS Device Control

Article • 03/14/2023

The host uses REMOTE_NDIS_QUERY_MSG and REMOTE_NDIS_SET_MSG to control the operation of the Remote NDIS device. An NDIS object ID (OID) is used with each such message to identify a device operational parameter or statistics counter. The lists of Remote NDIS OIDs are broken down into two groups: *general OID* and *802.3-specific OID*. Additionally, each group includes a subsection of statistic OID queries. The general OIDs are required of any networking device.

Remote NDIS INF Template

Article • 09/27/2024

Microsoft provides an NDIS miniport driver, Rndismp.sys, which implements the Remote NDIS message set and communicates with generic bus transport drivers, which in turn communicate with the appropriate bus driver. This NDIS miniport driver is implemented and maintained by Microsoft and is distributed as part of all supported Windows versions. You can find it in the %SystemRoot%\System32\drivers directory.

To use the Remote NDIS driver with a USB device, an IHV must provide an INF file according to one of the following templates:

- RNDIS INF template for NDIS 5.1 (Windows XP and later)
- RNDIS INF template for NDIS 6.0 (Windows 7 and later)

RNDIS INF template for NDIS 5.1 (Windows XP and later)

INF

```
; Remote NDIS template device setup file
; Copyright (c) Microsoft Corporation
;
; This is the template for the INF installation script
; for the RNDIS-over-USB host driver.
; This INF works for Windows XP SP2, Windows XP x64,
; Windows Server 2003 SP1 x86, x64, and ia64, and
 ; Windows Vista x86 and x64.
; This INF will work with Windows XP, Windows XP SP1,
; and Windows 2003 after applying specific hotfixes.

REMOTE_NDIS_INITIALIZE_MSG

Article • 03/03/2023

This message is sent by the host to a Remote NDIS device to initialize the network connection. It is sent through the control channel and only when the device is not in a state initialized by Remote NDIS.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000002.
4	4	MessageLength	Specifies in bytes the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.
12	4	MajorVersion	Specifies the Remote NDIS protocol version implemented by the host. The current specification uses RNDIS_MAJOR_VERSION = 1.
16	4	MinorVersion	Specifies the Remote NDIS protocol version implemented by the host. The current specification uses RNDIS_MINOR_VERSION = 0.
20	4	MaxTransferSize	Specifies the maximum size in bytes of any single bus data transfer that the host expects to receive from the device. Typically, each bus data transfer accommodates a single Remote NDIS message. However, the device may bundle several Remote NDIS messages that contain data packets into a single transfer (see REMOTE_NDIS_PACKET_MSG).

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_INITIALIZE_CMPLT

Article • 12/15/2021

The REMOTE_NDIS_INITIALIZE_CMPLT message is sent by the Remote NDIS device to the host in response to a REMOTE_NDIS_INITIALIZE_MSG message. In the REMOTE_NDIS_INITIALIZE_CMPLT message, the device reports its medium type, Remote NDIS version numbers, and its type (connectionless or connection-oriented or both).

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x80000002.
4	4	MessageLength	Specifies in bytes the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.
12	4	Status	Specifies RNDIS_STATUS_SUCCESS if the device initialized successfully; otherwise, it specifies an error code that indicates the failure.
16	4	MajorVersion	Specifies the highest Remote NDIS major protocol version supported by the device.
20	4	MinorVersion	Specifies the highest Remote NDIS minor protocol version supported by the device.
24	4	DeviceFlags	Specifies the miniport driver type as either connectionless or connection-oriented. This value can be one of the following: RNDIS_DF_CONNECTIONLESS 0x00000001 RNDIS_DF_CONNECTION_ORIENTED 0x00000002

Offset	Size	Field	Description
28	4	Medium	Specifies the medium supported by the device. Set to RNDIS_MEDIUM_802_3 (0x00000000)
32	4	MaxPacketsPerMessage	Specifies the maximum number of Remote NDIS data messages that the device can handle in a single transfer to it. This value should be at least one.
36	4	MaxTransferSize	Specifies the maximum size in bytes of any single bus data transfer that the device expects to receive from the host.
40	4	PacketAlignmentFactor	Specifies the byte alignment that the device expects for each Remote NDIS message that is part of a multimessage transfer to it. This value is specified in powers of 2. For example, this value is set to three to indicate 8-byte alignment. This value has a maximum setting of seven, which specifies 128-byte alignment.
44	4	AFListOffset	Reserved for connection-oriented devices. Set value to zero.
48	4	AFListSize	Reserved for connection-oriented devices. Set value to zero.

Remarks

The *Status* field should be set to RNDIS_STATUS_SUCCESS if the device initialized successfully; otherwise, it is set to an error code that indicates the failure. The device should return the highest Remote NDIS protocol version that it can support, in *MajorVersion* and *MinorVersion*--the combined version number should be less than or equal to the version number the host specified in the REMOTE_NDIS_INITIALIZE_MSG message.

The *AFListSize* and *AFListOffset* fields are relevant only for connection-oriented devices that include a call manager. Connectionless devices should set these fields to zero.

In this message, the Remote NDIS device indicates the following:

- Highest Remote NDIS protocol version number that the device can support. The combined version number should be less than or equal to the version number that the host specifies in the REMOTE_NDIS_INITIALIZE_MSG message. This allows the device to fall back to a compatibility mode when the host implements a Remote NDIS protocol version that is lower than that supported by the device.
- Maximum size in bytes of a single data transfer that the device expects to receive from the host. The device can specify the byte alignment it expects for each Remote NDIS message that is part of a multimessage transfer to it. This alignment value is specified in terms of powers of two. For example, this value is set to 3 to indicate 8-byte alignment.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_HALT_MSG

Article • 03/14/2023

This message is sent by the host to terminate the network connection. Unlike the other host-initiated control messages, the device does not respond to REMOTE_NDIS_HALT_MSG.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000003.
4	4	MessageLength	Specifies in bytes the total length of this message from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.

Remarks

It is optional for the device to implement REMOTE_NDIS_HALT_MSG. If implemented, the device sends this message to the host through the control channel only when the device is in a state initialized by Remote NDIS. The device must terminate all communication immediately after sending this message. Sending this message causes the device to enter a state not initialized by Remote NDIS.

All outstanding requests and packets should be discarded on receipt of this message.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.

Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_QUERY_MSG

Article • 03/03/2023

This message is sent to a Remote NDIS device from a host when it needs to query the device for its characteristics, statistics information, or status. The parameter or statistics counter being queried for is identified by means of an NDIS Object Identifier (OID). The host may send REMOTE_NDIS_QUERY_MSG to the device through the control channel at any time that the device is in either a state initialized by Remote NDIS. The Remote NDIS device will respond to this message by sending a REMOTE_NDIS_QUERY_CMPLT to the host.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000004.
4	4	MessageLength	Specifies in bytes the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.
12	4	Oid	Specifies the NDIS OID that identifies the parameter being queried.
16	4	InformationBufferLength	Specifies in bytes the length of the input data for the query. Set to zero when there is no OID input buffer.

Offset	Size	Field	Description
20	4	InformationBufferOffset	Specifies the byte offset, from the beginning of the *RequestId* field, at which input data for the query is located. Set to zero if there is no OID input buffer.
24	4	DeviceVcHandle	Reserved for connection-oriented devices. Set to zero.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_QUERY_CMPLT

Article • 03/03/2023

A Remote NDIS device will respond to a REMOTE_NDIS_QUERY_MSG message with a REMOTE_NDIS_QUERY_CMPLT message. This message is used to relay the result of a query for a device parameter or statistics counter to the host. The Remote NDIS device also returns the requested information to the host in this message.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x80000004.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is copied from the REMOTE_NDIS_QUERY_MSG being responded to.
12	4	Status	Specifies the status of processing the OID query request.
16	4	InformationBufferLength	Specifies, in bytes, the length of the response data for the query. Set to zero when there is no OID result buffer.
20	4	InformationBufferOffset	Specifies the byte offset, from the beginning of the *RequestId* field, at which response data for the query is located. Set to zero if there is no response data.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems.

	Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_SET_MSG

Article • 03/03/2023

This message is sent to a Remote NDIS device from a host, when it requires to set the value of some operational parameter on the device. The specific parameter being set is identified by means of an Object Identifier (OID), and the value it is to be set to is contained in an information buffer sent along with the message. The host may send REMOTE_NDIS_SET_MSG to the device through the control channel at any time that the device is in a state initialized by Remote NDIS. The Remote NDIS device will respond to this message by sending a REMOTE_NDIS_SET_CMPLT to the host.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000005.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.
12	4	Oid	Specifies the NDIS OID that identifies the parameter being set.
16	4	InformationBufferLength	Specifies, in bytes, the length of the input data for the request.
20	4	InformationBufferOffset	Specifies the byte offset, from the beginning of the *RequestId* field, at which input data for the request is located.

Offset	Size	Field	Description
24	4	DeviceVcHandle	Reserved for connection-oriented devices. Set to zero.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.

REMOTE_NDIS_SET_CMPLT

Article • 03/03/2023

A Remote NDIS device will respond to a REMOTE_NDIS_SET_MSG message with a REMOTE_NDIS_SET_CMPLT message. This message is used to relay the result of setting the value of a device operational parameter to the host.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x80000005.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is copied from the REMOTE_NDIS_SET_MSG being responded to.
12	4	Status	Specifies the status of processing the OID set request.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_RESET_MSG

Article • 03/03/2023

This message is sent to a Remote NDIS device from a host to reset the device and return status. The host may send REMOTE_NDIS_RESET_MSG to the device through the control channel at any time that the device is in a state initialized by Remote NDIS. The Remote NDIS device will respond to this message by sending a REMOTE_NDIS_RESET_CMPLT to the host.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000006.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	Reserved	Reserved. Set to zero.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_RESET_CMPLT

Article • 03/03/2023

A Remote NDIS device will respond to a REMOTE_NDIS_RESET_MSG message from the host by resetting the device and returning the status of the request in the REMOTE_NDIS_RESET_CMPLT message.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x80000006.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	Status	Specifies the status of processing the Reset request.
12	4	AddressingReset	Indicates if addressing information (multicast address list, packet filter) has been lost during the concluded reset operation. If the device requires the host to resend addressing information, set this field to one; otherwise set it to zero.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_INDICATE_STATUS_MSG

Article • 03/03/2023

This message is sent from a Remote NDIS device to a host to indicate a change in the status of the device. A REMOTE_NDIS_INDICATE_STATUS_MSG message can also be used to indicate an error event, such as an unrecognized message. The Remote NDIS device may send this message at any time that it is in a state initialized by Remote NDIS. There is no response to this message.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000007.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	Status	Specifies the current status of the host request.
12	4	StatusBufferLength	Specifies the length of the status data, in bytes.
16	4	StatusBufferOffset	Specifies the byte offset, from the beginning of this message, at which Rndis_Diagnostic_Info status data for the device indication is located.

Remarks

The most common use of REMOTE_NDIS_INDICATE_STATUS_MSG is to indicate the state of the link for an 802.3 device. A status value of RNDIS_STATUS_MEDIA_CONNECT indicates a transition from disconnected (for example no 802.3 link pulse) to connected state (802.3 link pulse detected). A status value of RNDIS_STATUS_MEDIA_DISCONNECT indicates a transition from connected to disconnected state. The device must send

REMOTE_NDIS_INDICATE_STATUS_MSG with one of these values every time the 802.3 link state changes. No status buffer is required to return these two common indications.

In the specific case where this message is sent in response to a host message that the device could not handle, the *Status* field must be set to RNDIS_STATUS_INVALID_DATA, and the Rndis_Diagnostic_Info status buffer is formatted as follows.

Offset	Size	Field	Description
0	4	DiagStatus	Contains status information about the error itself (for example, RNDIS_STATUS_NOT_SUPPORTED)
4	4	ErrorOffset	Specifies the zero-based byte offset in the original message at which the error was detected.

If the error condition was caused by an Remote NDIS message (for example, the device can't recognize a particular RNDIS message), then the device should append the original message at the end of the status message defined above.

This message is used to report an error condition only in circumstances where the device is not able to generate a response message with appropriate status. Examples of appropriate usage are:

- On receiving a message with unsupported message type.
- On receiving a REMOTE_NDIS_PACKET_MSG with unacceptable contents.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_KEEPALIVE_MSG

Article • 03/03/2023

The host sends this message periodically when there has been no other control or data traffic from the device to the host for the bus-defined *KeepAliveTimeoutPeriod*. This message is sent by the host at least every RNDIS_KEEPALIVE_TIMEOUT seconds, in the absence of other message traffic, to detect the state of the remote device. The remote device may use the same message in the reverse direction, but it is not required.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x00000008.
4	4	MessageLength	Specifies in bytes the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.

Remarks

The host will not send a REMOTE_NDIS_KEEPALIVE_MSG message until RNDIS_KEEPALIVE_TIMEOUT seconds have elapsed since the last message received from the remote device. This avoids unnecessary exchange of keep-alive messages when the communication channel is active.

The device can optionally send this message to the host as well. For example, the device may use this message to trigger a response from the host for computing round-trip delay time. If implemented, the device must send REMOTE_NDIS_KEEPALIVE_MSG through the control channel and only when the device is in a state initialized by Remote NDIS.

The host sends a **REMOTE_NDIS_KEEPALIVE_MSG** message to the device through the control channel to check the health of the device. When the device is in a state initialized by Remote NDIS, the host sends this message periodically when there has been no other control or data traffic from the device to the host for the *KeepAliveTimeoutPeriod*. *KeepAliveTimeoutPeriod* is bus-dependent and is defined in the appropriate bus-mapping specifications.

Upon receiving this message, the remote device must return a response whose *Status* field indicates whether the device solicits a **REMOTE_NDIS_RESET_MSG** message from the host.

The device does not have to perform any specific action if it stops seeing **REMOTE_NDIS_KEEPALIVE_MSG** messages from the host.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

REMOTE_NDIS_KEEPALIVE_CMPLT

Article • 03/03/2023

A Remote NDIS device will respond to a REMOTE_NDIS_KEEPALIVE_MSG message from the host by sending back a REMOTE_NDIS_KEEPALIVE_CMPLT response message. If the returned Status is not RNDIS_STATUS_SUCCESS, the host will send REMOTE_NDIS_RESET_MSG to reset the device.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x80000008.
4	4	MessageLength	Specifies, in bytes, the total length of this message, from the beginning of the message.
8	4	RequestId	Specifies the Remote NDIS message ID value. This value is used to match messages sent by the host with device responses.
12	4	Status	Specifies the current status of the device. If the returned *Status* is not RNDIS_STATUS_SUCCESS, the host will send an REMOTE_NDIS_RESET_MSG message to reset the device.

Remarks

If the device implements the option of sending REMOTE_NDIS_KEEPALIVE_MSG, the host will respond with REMOTE_NDIS_KEEPALIVE_CMPLT through the control channel.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems.

	Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

Remote NDIS Data Message

Article • 03/14/2023

A Remote NDIS device encapsulates NDIS packets to transfer them across the data channel. Data messages are used to do this because they can contain out-of-band (OOB) data or per-packet information.

The data message that is used to encapsulate data for transfer across the data channel is described in the following topic:

REMOTE_NDIS_PACKET_MSG

REMOTE_NDIS_PACKET_MSG

Article • 03/03/2023

REMOTE_NDIS_PACKET_MSG encapsulates NDIS data packets to form a single data message.

Concatenating multiple REMOTE_NDIS_PACKET_MSG elements forms a multipacket message. Each individual REMOTE_NDIS_PACKET_MSG component is constructed as described below. The difference from the single-packet message is that the *MessageLength* field in each REMOTE_NDIS_PACKET_MSG header includes some additional padding bytes. These padding bytes are appended to all but the last REMOTE_NDIS_PACKET_MSG so that the succeeding REMOTE_NDIS_PACKET_MSG starts at an appropriate byte boundary. For messages sent from the device to the host, this padding should result in each REMOTE_NDIS_PACKET_MSG starting at a byte offset that is a multiple of 8 bytes starting from the beginning of the multipacket message. When the host sends a multipacket message to the device, it will adhere to the *PacketAlignmentFactor* that the device specifies.

The REMOTE_NDIS_PACKET_MSG format is defined in the following table.

Offset	Size	Field	Description
0	4	MessageType	Specifies the type of message being sent. Set to 0x1.
4	4	MessageLength	Message length in bytes, including appended packet data, OOB data, per-packet information data, and both internal and external padding.
8	4	DataOffset	Specifies the offset in bytes from the start of the DataOffset field of this message to the start of the data. This is an integer multiple of 4.
12	4	DataLength	Specifies the number of bytes in the data content of this message.

Offset	Size	Field	Description
16	4	OOBDataOffset	Specifies the offset in bytes of the first OOB data record from the start of the *DataOffset* field of this message. Set to zero if there is no OOB data. Otherwise, this is an integer multiple of 4.
20	4	OOBDataLength	Specifies in bytes the total length of the OOB data.
24	4	NumOOBDataElements	Specifies the number of OOB records in this message.
28	4	PerPacketInfoOffset	Specifies in bytes the offset from the beginning of the *DataOffset* field in the REMOTE_NDIS_PACKET_MSG data message to the start of the first per-packet information data record. Set to zero if there is no per-packet data. Otherwise, this is an integer multiple of 4.
32	4	PerPacketInfoLength	Specifies in bytes the total length of the per-packet information contained in this message.
36	4	VcHandle	Reserved for connection-oriented devices. Set to zero.
40	4	Reserved	Reserved. Set to zero.

The format of a single OOB data record is indicated in the following table.

Offset	Size	Field	Description
0	4	Size	Length in bytes of this OOB header and appended OOB data and padding. This is an integer multiple of 4.

Offset	Size	Field	Description
4	4	Type	None defined for 802.3 devices.
8	4	ClassInformationOffset	The byte offset from the beginning of this OOB data record to the beginning of the OOB data.
(N)	...	OOB Data	OOB Data; consult Microsoft Windows Driver Development Kit (DDK) documentation for more information.

Note (N) is equal to the value of *ClassInformationOffset*.

The following table defines the format of a per-packet information data record.

Offset	Size	Field	Description
0	4	Size	Length in bytes of this per-packet header and appended per-packet data and padding. This value is an integer multiple of 4.
4	4	Type	Set to one of the legal values for NDIS_PER_PACKET_INFO_FROM_PACKET, as described in the Windows 2000 Driver Development Kit (DDK).
8	4	PerPacketInformationOffset	The byte offset from the beginning of this per-packet information data record to the beginning of the per-packet information data.
(N)	...	Per-Packet Data	Per-Packet Data; consult Windows 2000 DDK documentation for more information.

Note (N) is equal to the value of *PerPacketInformationOffset*.

Remarks

Each REMOTE_NDIS_PACKET_MSG may contain one or more OOB data records. *NumOOBDataElements* indicates the number of OOB data records in this message. The OOB data records must appear in sequence. The *OOBDataLength* field indicates the length in bytes of the entire OOB data block. The *OOBDataOffset* field indicates the byte offset from the beginning of the *DataOffset* field to the beginning of the OOB data block. For more information about OOB packet data, see the NDIS specification in the Windows 2000 DDK.

If multiple OOB data blocks are attached to a REMOTE_NDIS_PACKET_MSG message, each subsequent OOB data record must immediately follow the previous OOB record's data.

No OOB information is currently defined for 802.3 devices.

Each REMOTE_NDIS_PACKET_MSG may contain one or more per-packet-info data records. Per-packet-info is used to convey packet metadata, such as TCP checksum. The *PerPacketInfoOffset* field indicates the byte offset from the beginning of the *DataOffset* field to the beginning of the per-packet information data record. The *OOBDataLength* field indicates the byte length of the per-packet information data record. For more information about per-packet information data, see the Windows 2000 DDK.

If there are multiple per-packet information data blocks, each subsequent per-packet information data record must immediately follow the previous per-packet information record's data.

A Remote NDIS device must send and receive data through NDIS data packets. The bus that the device uses determines how these packets are passed from host to device and device to host. It could be shared memory or, in the case of USB, Isoch and Bulk pipes. NDIS packets may also contain out-of-band (OOB) data as well as the data that goes across the network.

A Remote NDIS device transfers NDIS packets, encapsulated as **REMOTE_NDIS_PACKET_MSG** across the data channel. Both connectionless (such as 802.3) and connection-oriented (such as ATM) devices use the same packet message structure to facilitate common code for packet processing. Each **REMOTE_NDIS_PACKET_MSG** message contains information about a single network data unit (such s an Ethernet 802.3 frame).

For more information about out-of-band packet data or per-packet-info data, see the Windows 2000 DDK NDIS sections.

Requirements

Version	Available in Microsoft Windows XP and later versions of the Windows operating systems. Also available in Windows 2000 as redistributable binaries.
Header	Rndis.h (include Rndis.h)

Multipacket Messages

Article • 12/15/2021

Multiple REMOTE_NDIS_PACKET_MSG messages may be sent in a single transfer, in either direction. A multipacket message is formed by concatenating multiple **REMOTE_NDIS_PACKET_MSG** elements. The maximum length of such a transfer is governed by the *MaxTransferSize* parameter passed in the REMOTE_NDIS_INITIALIZE_MSG and response messages. The host will also limit the number of messages it bundles into a single transfer to the *MaxPacketsPerMessage* parameter returned by the device in the REMOTE_NDIS_INITIALIZE_CMPLT response message.

The difference from the single-packet message case is that the *MessageLength* field in each REMOTE_NDIS_PACKET_MSG header includes some additional padding bytes. These padding bytes are added to all but the last **REMOTE_NDIS_PACKET_MSG** such that the succeeding REMOTE_NDIS_PACKET_MSG starts at an appropriate byte boundary. For messages sent from the device to the host, this padding should result in each REMOTE_NDIS_PACKET_MSG starting at a byte offset that is a multiple of 8 bytes starting from the beginning of the multipacket message. When the host sends a multipacket message to the device, it will adhere to the *PacketAlignmentFactor* specified by the device in the REMOTE_NDIS_INITIALIZE_CMPLT response message.

Note that neither the combined length of a multipacket message nor the number of REMOTE_NDIS_PACKET_MSG elements in a combined message is given explicitly in any Remote NDIS defined field. The combined length is implicit in the bus-specific transfer mechanism, and the host or device must walk the *MessageLength* fields of the combined message to determine the number of combined messages.

The following table is an example of a multipacket message that is made up of two REMOTE_NDIS_PACKET_MSGs, sent from the host to the device. During the REMOTE_NDIS_INITIALIZE_MSG exchange, the device requested a *PacketAlignmentFactor* of 3 (an alignment along an 8-byte boundary).

Offset	Size	Field	Value
0	4	MessageType	0x1
4	4	MessageLength	72 (includes 2 padding bytes; see below)
8	4	DataOffset	36

Offset	Size	Field	Value
12	4	DataLength	26
16	4	OOBDataOffset	0
20	4	OOBDataLength	0
24	4	NumOOBDataElements	0
28	4	PerPacketInfoOffset	0
32	4	PerPacketInfoLength	0
36	4	VcHandle	0
40	4	Reserved	0
44	26	Payload (data)	Some network data of 26 bytes in length
70	2	Padding	Doesn't matter - unused
72	4	MessageType (start of second REMOTE_NDIS_PACKET_MSG)	0x1
76	4	MessageLength	60
80	4	DataOffset	36
84	4	DataLength	16
88	4	OOBDataOffset	0
92	4	OOBDataLength	0
96	4	NumOOBDataElements	0
100	4	PerPacketInfoOffset	0
104	4	PerPacketInfoLength	0
108	4	VcHandle	0
112	4	Reserved	0
116	16	Payload (data)	Some network data of 16 bytes in length

Setting Device-Specific Parameters

Article • 12/15/2021

It is expected that most Remote NDIS devices will function well without the need to configure parameters on the host. However, there may be cases where proper network operation requires some configuration on the host. If the device supports configurable parameters, then it should include the following optional OID in the list of supported OIDs it reports in response to a query for OID_GEN_SUPPORTED_LIST:

C++

```
#define OID_GEN_RNDIS_CONFIG_PARAMETER 0x0001021B
```

If the device supports the OID_GEN_RNDIS_CONFIG_PARAMETER OID, the host uses it to set device-specific parameters, soon after the device enters a state initialized by Remote NDIS from the uninitialized state. The host will send zero or more REMOTE_NDIS_SET_MSGs to the device, with OID_GEN_RNDIS_CONFIG_PARAMETER as the OID value to set. Each such **REMOTE_NDIS_SET_MSG** corresponds to one device-specific parameter that is configured on the host.

The *InformationBuffer* associated with each such **REMOTE_NDIS_SET_MSG** has the following format. Note that the Offset values are relative to the beginning of the information buffer.

Offset	Size	Field	Description
0	4	ParameterNameOffset	Specifies the byte offset from the beginning of the ParameterNameOffset field at which a Unicode character string representing the parameter name is located. The string does not include a NULL terminator.
4	4	ParameterNameLength	Specifies the byte length of the parameter name string.

Offset	Size	Field	Description
8	4	ParameterType	Specifies the data type of the parameter value. This is one of the following: 0 - numeric value; 2 - string value.
12	4	ParameterValueOffset	Specifies the byte offset from the beginning of the ParameterNameOffset field at which the parameter value is located.
16	4	ParameterValueLength	Specifies the byte length of the parameter value.

The device sends a REMOTE_NDIS_SET_CMPLT in response to each REMOTE_NDIS_SET_MSG, after applying the parameter value. If the parameter setting is acceptable, it returns a status of RNDIS_STATUS_SUCCESS in the response. If the parameter setting is not acceptable, and the device cannot apply a useful default value for this parameter, then the device returns an appropriate error status value (see section on status values). If an error status is returned, then the host will initiate a halt process for the device.

Device-specific parameters are expected to be configured in the Windows registry. The keys that define parameter values are typically created in the registry during the process of device installation. The list of keys, type information, default values and optional range of valid values are specified in the INF file for the device. For more information about using an INF to set up configuration parameters in the registry for network devices, consult the Windows 2000 Driver Development Kit (DDK).

Example Connectionless (802.3) Initialization Sequence

Article • 12/15/2021

This section describes the general order of events that a device can expect upon startup as a Remote NDIS connectionless device. Because the basic operation of Remote NDIS is the same, regardless of the underlying bus, the require bus enumeration and start up process has been left out of the example.

Host	Device	Description
REMOTE_NDIS_INITIALIZE_MSG		Hosts sends Remote NDIS Initialization message to device.
	REMOTE_NDIS_INITIALIZE_CMPLT	Device response with Initialize Complete message.
Receiving. Successful Initialization		Host starts accepting data on incoming data channel. (Example: on USB starts doing reads on IN pipe).
REMOTE_NDIS_QUERY_MSG AND REMOTE_NDIS_SET_MSG	REMOTE_NDIS_QUERY_CMPLT OR REMOTE_NDIS_SET_CMPLT	Host initiates a series of sets and queries to determine state of device and to setup initial parameters. The device responses appropriately with the correct complete messages. The following NDIS OIDs may be queried: OID_802_3_CURRENT_ADDRESS, OID_802_3_MAXIMUM_LIST_SIZE, and so on.
REMOTE_NDIS_SET_MSG		Host sends an OID_GEN_CURRENT_PACKET_FILTER OID with a nonzero filter value to the device. At this point the device should start sending data packets on the incoming data channel. The host will also start sending data packets on the outgoing data channel.

Remote NDIS OIDs

Article • 03/14/2023

This section lists the required and optional NDIS OIDs for Remote NDIS Ethernet devices. The list takes into account the unique properties of a Remote NDIS device and the Remote NDIS miniport driver, so the list is not identical to the list that a normal NDIS connectionless miniport driver would support. Some OIDs are both *set* and *query* OIDs; if a mandatory OID is defined as both, then it must be supported by a Remote NDIS device for both REMOTE_NDIS_SET_MSG and REMOTE_NDIS_QUERY_MSG. For a detailed explanation of the OIDs, see the Microsoft Windows Driver Development Kit (DDK).

The following lists of Remote NDIS OIDs are broken down into two groups -- general OID and 802.3 specific OID. Additionally, each group includes a subsection of statistic OID queries. The general OIDs are required for any networking device.

- General OIDs
- General Statistic OIDs
- 802.3 OIDs
- 802.3 Statistic OIDs
- Optional Power Management OIDs
- Optional Network Wake Up OIDs

General OIDs

Article • 12/15/2021

The following table lists the general OIDs for Remote NDIS Ethernet devices.

Support	OID	Description
Required	OID_GEN_SUPPORTED_LIST	List of supported OIDs.
Required	OID_GEN_HARDWARE_STATUS	Hardware status.
Required	OID_GEN_MEDIA_SUPPORTED	Media types supported (encoded).
Required	OID_GEN_MEDIA_IN_USE	Media types in use (encoded).
Required	OID_GEN_MAXIMUM_FRAME_SIZE	Maximum frame size in bytes.
Required	OID_GEN_LINK_SPEED	Link speed in units of 100 bps.
Required	OID_GEN_TRANSMIT_BLOCK_SIZE	Minimum amount of storage, in bytes, that a single packet occupies in the transmit buffer space of the NIC.
Required	OID_GEN_RECEIVE_BLOCK_SIZE	Amount of storage, in bytes, that a single packet occupies in the receive buffer space of the NIC.
Required	OID_GEN_VENDOR_ID	Vendor NIC code.
Required	OID_GEN_VENDOR_DESCRIPTION	Vendor network card description.
Required	OID_GEN_VENDOR_DRIVER_VERSION	Vendor-assigned version number of driver.
Required	OID_GEN_CURRENT_PACKET_FILTER	Current packet filter (encoded).
Required	OID_GEN_MAXIMUM_TOTAL_SIZE	Maximum total packet length in bytes.

Support	OID	Description
Optional	OID_GEN_RNDIS_CONFIG_PARAMETER	Device-specific configuration parameter (set only).
Optional	OID_GEN_PHYSICAL_MEDIUM	Information about the underlying physical medium.
Required	OID_GEN_MEDIA_CONNECT_STATUS	Status of the NIC network connection.
Optional	OID_GEN_MAC_OPTIONS	A bitmask that specifies optional properties of the NIC. Must be supported only by NICs that support 802.1p packet priority.

General Statistic OIDs

Article • 12/15/2021

The following table lists the general statistic OIDs for Remote NDIS Ethernet devices.

Support	OID	Description
Required	OID_GEN_XMIT_OK	Frames transmitted without errors
Required	OID_GEN_RCV_OK	Frames received without errors
Required	OID_GEN_XMIT_ERROR	Frames transmitted with errors
Required	OID_GEN_RCV_ERROR	Frames received with errors
Required	OID_GEN_RCV_NO_BUFFER	Frame missed, no buffers
Optional	OID_GEN_DIRECTED_BYTES_XMIT	Directed bytes transmitted without errors
Optional	OID_GEN_DIRECTED_FRAMES_XMIT	Directed frames transmitted without errors
Optional	OID_GEN_MULTICAST_BYTES_XMIT	Multicast bytes transmitted without errors
Optional	OID_GEN_MULTICAST_FRAMES_XMIT	Multicast frames transmitted without errors
Optional	OID_GEN_BROADCAST_BYTES_XMIT	Broadcast bytes transmitted without errors
Optional	OID_GEN_BROADCAST_FRAMES_XMIT	Broadcast frames transmitted without errors
Optional	OID_GEN_DIRECTED_BYTES_RCV	Directed bytes received without errors
Optional	OID_GEN_DIRECTED_FRAMES_RCV	Directed frames received without errors
Optional	OID_GEN_MULTICAST_BYTES_RCV	Multicast bytes received without errors
Optional	OID_GEN_MULTICAST_FRAMES_RCV	Multicast frames received without errors

Support	OID	Description
Optional	OID_GEN_BROADCAST_BYTES_RCV	Broadcast bytes received without errors
Optional	OID_GEN_BROADCAST_FRAMES_RCV	Broadcast frames received without errors
Optional	OID_GEN_RCV_CRC_ERROR	Frames received with circular redundancy check (CRC) or frame check sequence (FCS) errors
Optional	OID_GEN_TRANSMIT_QUEUE_LENGTH	Length of transmit queue

802.3 OIDs

Article • 12/15/2021

The following table lists the specific 802.3 OIDs for Remote NDIS Ethernet devices.

Support	OID	Description
Required	OID_802_3_PERMANENT_ADDRESS	Permanent station address
Required	OID_802_3_CURRENT_ADDRESS	Current station address
Required	OID_802_3_MULTICAST_LIST	Current multicast address list
Optional	OID_802_3_MAC_OPTIONS	NIC flags (encoded)
Required	OID_802_3_MAXIMUM_LIST_SIZE	Maximum size of multicast address list

802.3 Statistic OIDs

Article • 12/15/2021

The following table lists the 802.3 statistic OIDs for Remote NDIS Ethernet devices.

Support	OID	Description
Optional	OID_802_3_XMIT_DEFERRED	Frames transmitted after deferral
Optional	OID_802_3_XMIT_MAX_COLLISIONS	Frames not transmitted due to collisions
Optional	OID_802_3_RCV_OVERRUN	Frames not received due to overrun
Optional	OID_802_3_XMIT_UNDERRUN	Frames not transmitted due to underrun
Optional	OID_802_3_XMIT_HEARTBEAT_FAILURE	Frames transmitted with heartbeat failure
Optional	OID_802_3_XMIT_TIMES_CRS_LOST	Times carrier sense signal lost during transmission
Optional	OID_802_3_XMIT_LATE_COLLISIONS	Late collisions detected

Optional Power Management OIDs

Article • 12/15/2021

For NDIS to consider a device power-management -- aware, it must respond to the three power management OIDs listed in the following table. If the device returns a failure status code in response to a query for OID_PNP_CAPABILITIES, then the host will consider the device as not being power manageable. NDIS decides whether to query this OID based on the underlying bus technology that the Remote NDIS device is connected to. Some buses are power-manageable, such as USB, so it is expected that these types of Remote NDIS devices will support the minimal OIDs to be considered power-manageable.

Support	OID	Description
Optional	OID_PNP_CAPABILITIES	The NIC's Power Management abilities
Optional	OID_PNP_QUERY_POWER	A query to determine whether the device can transition to a specific power state.
Optional	OID_PNP_SET_POWER	A command to set the device to specified power state

Optional Network Wake Up OIDs

Article • 12/15/2021

To support network wake up events, a Remote NDIS device must additionally support the OID_PNP_ENABLE_WAKE_UP OID that is used by both the network protocols (TCP/IP) and NDIS to enable the wake up capabilities. Additionally, the options listed in the following table are available to enable specific types of wake up patterns. For further details, consult the Microsoft Windows 2000 Driver Development Kit (DDK).

Support	OID	Description
Optional	OID_PNP_ENABLE_WAKE_UP	The Remote NDIS device's wake-up capabilities that can be enabled
Optional	OID_PNP_ADD_WAKE_UP_PATTERN	Wake-up patterns that the Remote NDIS miniport driver should load into the device
Optional	OID_PNP_REMOVE_WAKE_UP_PATTERN	Wake-up patterns that the Remote NDIS miniport driver should remove from the device

Remote NDIS Version

Article • 03/14/2023

The following table defines the Remote NDIS protocol version identifiers exchanged between host and device.

Version Identifier	Value	Description
RNDIS_MAJOR_VERSION	1	Remote NDIS Major Version
RNDIS_MINOR_VERSION	0	Remote NDIS Minor Version

Status Values

Article • 12/15/2021

The Remote NDIS status values are generally equivalent to the 32-bit status values that are defined in the Microsoft Windows 2000 Driver Development Kit (DDK). The specific Remote NDIS status values used in this specification are listed below, others can be inferred from the Windows 2000 DDK or online documentation. A device may return any semantically correct Remote NDIS status value in a *Status* field of a message that it generates.

Status Identifier	Value	Description
RNDIS_STATUS_SUCCESS	0x00000000	Success
RNDIS_STATUS_FAILURE	0xC00000001	Unspecified error (equivalent to STATUS_UNSUCCESSFUL)
RNDIS_STATUS_INVALID_DATA	0xC0010015	Invalid data error
RNDIS_STATUS_NOT_SUPPORTED	0xC00000BB	Unsupported request error
RNDIS_STATUS_MEDIA_CONNECT	0x4001000B	Device is connected to network medium (equivalent to NDIS_STATUS_MEDIA_CONNECT from Windows 2000 DDK)
RNDIS_STATUS_MEDIA_DISCONNECT	0x4001000C	Device is disconnected from network medium (equivalent to NDIS_STATUS_MEDIA_DISCONNECT from Windows 2000 DDK)
RNDIS_STATUS_Xxx	...	Equal to NDIS_STATUS_Xxx values defined in Windows 2000 DDK or online documentation

Remote NDIS To USB Mapping overview

Article • 09/27/2024

A USB Remote NDIS device is implemented as a USB Communication Device Class (CDC) device with two interfaces. A Communication Class interface, of type Abstract Control, and a Data Class interface combine to form a single functional unit representing the USB Remote NDIS device. The Communication Class interface includes a single endpoint for event notification and uses the shared bidirectional Control endpoint for control messages. The Data Class interface includes two bulk endpoints for data traffic.

> ⓘ **Note**
>
> An understanding of the Universal Serial Bus (USB) Specification versions 1.1 and 2.0 is required. The USB Communication Device Class (CDC) Specifications are suggested as references. These documents can be found at https://www.usb.org.

This section includes the following topics:

USB-Level Initialization

USB-Level Termination

Control Channel Characteristics

Data Channel Characteristics

Power Management

Timer Constants

USB 802.3 Device Sample

Feedback

USB-Level Initialization

Article • 12/15/2021

The host issues standard USB requests to obtain a set of standard USB descriptors for the device. The relevant portions of those descriptors are given below. See the USB Specification for generic USB device initialization.

USB Device Descriptor

Article • 12/15/2021

The device returns a USB Device Descriptor as defined in the USB Specification. The following table defines the prominent fields of the USB Device Descriptor.

Offset (bytes)	Field	Size (bytes)	Value	Description
4	bDeviceClass	1	02h	Communication Device Class code.
5	bDeviceSubClass	1	00h	Communication Device Subclass code, unused at this time.
6	bDeviceProtocol	1	00h	Communication Device Protocol code, unused at this time.

USB Configuration Descriptor

Article • 12/15/2021

The device returns a Configuration Descriptor as defined in the USB Specification. See the USB Specification for details.

Communication Class Interface

Article • 12/15/2021

The Communication Class interface is described by a USB interface descriptor, three class-specific descriptors, and an endpoint descriptor for the notification endpoint. The notification endpoint descriptor is a standard USB Interrupt-type IN endpoint descriptor whose **wMaxPacketSize** field is 8 bytes. The following table defines the prominent fields of the Communication Class interface descriptor.

Offset (bytes)	Field	Size (bytes)	Value	Description
5	bInterfaceClass	1	02h	Communication Interface Class code.
6	bInterfaceSubClass	1	02h	Communication Interface Class SubClass code for Abstract Control Model.
7	bInterfaceProtocol	1	FFh	Communication Interface Class Protocol code for vendor specific protocol.

Data Class Interface

Article • 12/15/2021

The Data Class interface is described by a standard USB Interface Descriptor followed by two endpoint descriptors. The two endpoint descriptors in the Data Class interface define standard USB Bulk-type endpoints: one Bulk-IN and one Bulk-OUT. The following table defines the prominent fields of the Data Class Interface Descriptor.

Offset (bytes)	Field	Size (bytes)	Value	Description
5	bInterfaceClass	1	0Ah	Data Interface Class code.
6	bInterfaceSubClass	1	00h	Data Class SubClass code.
7	bInterfaceProtocol	1	00h	Data Class Protocol code.

USB-Level Termination

Article • 12/15/2021

See the USB Specification for a description of generic USB bus-level termination.

Control Channel Characteristics

Article • 12/15/2021

The Control channel for the device is its USB Control endpoint. A control message from the host to the device is sent as a SEND_ENCAPSULATED_COMMAND transfer. This transfer is defined in the following table.

BmRequestType	bRequest	wValue	wIndex	wLength	Data
0x21	0x00	0x0000	*bInterfaceNumber* field of Communication Class interface descriptor	Byte length of control message block	Control message block

The host does not continuously poll the USB Control endpoint for input control messages. Upon placing a control message on its Control endpoint, the device must return a notification on the Communication Class interface's Interrupt IN endpoint, which is polled by the host whenever the device can return control messages. The transfer from the device's interrupt IN endpoint to the host is a standard USB Interrupt IN transfer. The only defined device notification is the RESPONSE_AVAILABLE notification, defined in the following table.

Offset (bytes)	Length (bytes)	Field	Data
0	4	Notification	RESPONSE_AVAILABLE (0x00000001)
4	4	Reserved	0

Upon receiving the RESPONSE_AVAILABLE notification, the host reads the control message from the Control endpoint using a GET_ENCAPSULATED_RESPONSE transfer, defined in the following table.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0xA1	0x01	0x0000	*bInterfaceNumber* field of Communication Class interface descriptor	0x0400 (this is the minimum byte length of the buffer posted by host)	Control message block

If for some reason the device receives a GET_ENCAPSULATED_RESPONSE and is unable to respond with a valid data on the Control endpoint, then it should return a one-byte packet set to 0x00, rather than stalling the Control endpoint.

Data Channel Characteristics

Article • 12/15/2021

The data channel for the device consists of the *Bulk* IN and OUT endpoints in the *Data Class* interface.

A single USB data transfer in either direction may consist of a single REMOTE_NDIS_PACKET_MSG or a longer multipacket message.

The USB transfer to send a data message from the host to the device is a standard USB bulk transfer to the Bulk OUT endpoint of the Data Class interface.

The USB transfer to send a data message from the device to the host is a standard USB bulk transfer from the Bulk IN endpoint of the Data Class interface. The host will read up to the number of bytes indicated by the *MaxTransferSize* field of REMOTE_NDIS_INITIALIZE_MSG, which will be no greater than 0x4000 bytes for a USB 1.1 device.

USB Short Packets

Article • 12/15/2021

USB passes data over the wire in the form of USB packets, which should not be confused with NDIS or networking packets. The maximum length of a USB packet to or from a USB endpoint is limited to the value of the **wMaxPacketSize** field of the endpoint's descriptor. For bulk pipes the maximum packet size is 64 bytes. Due to constraints of certain USB host controllers, there is a penalty associated with using short USB packets (for example, those of less then 64 bytes, when streaming data).

To work around this limitation, Remote NDIS USB devices may append zero-byte padding to data messages so that a short packet will not occur (within the constraints of the **MaxTransferSize** field of REMOTE_NDIS_INITIALIZE_MSG). The **MessageLength** field of the final REMOTE_NDIS_PACKET_MSG does not include these appended padding bytes.

If the device has transmitted its last available REMOTE_NDIS_PACKET_MSG (so no more are left in the device's queue), then it is acceptable to send a short USB packet.

If the last REMOTE_NDIS_PACKET_MSG of a device-send Remote NDIS data message (without any zero-byte padding) ends with a USB packet whose length is exactly the **wMaxPacketSize** for that endpoint, then the device may send an additional one-byte zero packet as an appended part of the transfer. Some device implementations are simplified by this allowance.

Similarly, some device-side USB chipsets do not detect the end of a received USB transfer that ends with a USB packet whose length is the **wMaxPacketSize** for that endpoint. For this reason, the host must append a one-byte zero packet to a data transfer that otherwise would have a length that is a multiple of the **wMaxPacketSize** of the receiving endpoint. USB Remote NDIS devices must tolerate the appended byte. The **MessageLength** field of the final REMOTE_NDIS_PACKET_MSG does not include this appended byte.

Flow Control

Article • 12/15/2021

Flow control for a USB Remote NDIS device is defined by the USB Specification.

Since all communication on USB is based on a host to device transaction, all the host must do to slow the flow of data is stop issuing IN tokens to the device on the bulk pipe. If the device needs to assert flow control, then it should NAK data transfers from the host until it is able to process data again. For a detailed explanation of this process, review Section 8.4.4 in the USB Specification, version 1.1.

USB Remote NDIS power management

Article • 03/14/2023

A USB Remote NDIS device must support the Power Management OIDs as well as Network wake-up OIDs that are listed in the Microsoft Windows 2000 Driver Development Kit (DDK) under NDIS OIDs. See the USB specification for a description of USB bus-level power management.

Timer Constants

Article • 12/15/2021

The **ControlTimeoutPeriod** for a USB Remote NDIS device is 10 seconds.

The **KeepAliveTimeoutPeriod** for a USB Remote NDIS device is 5 seconds.

USB 802.3 Device Sample

Article • 03/22/2024

This section contains a sample set of descriptors for a USB Remote NDIS Ethernet Device. It includes a CDC Communication Class interface and a CDC Data Class interface. The Device Descriptor is returned independently. The Configuration descriptor and all following descriptors are returned as a single block in the order shown.

Control messages are sent on the Control endpoint. Notification messages are sent on the Interrupt In endpoint in the CDC Communication Class interface. Data messages are sent on the Bulk In and Bulk Out endpoints in the CDC Data Class interface. String descriptors are not shown.

The Remote NDIS implementation in Windows Millennium Edition assumes that the Communication Class interface precedes the Data Class interface. Vendors should choose this descriptor ordering so that devices initialize correctly on Windows Millennium Edition.

If any portion of this sample contradicts a controlling specification, follow the specification.

This sample in this section includes:

Device Descriptor

Configuration Descriptor

Interface Descriptor for Communication Class Interface

Notification Endpoint Descriptor

Interface Descriptor for Data Class Interface

Data In Endpoint Descriptor

Data Out Endpoint Descriptor

6	bInterval	1	0x00	Unused

Kernel Mode SDK Topics for Network Drivers

Article • 12/15/2021

This section lists header files and topics for kernel mode Windows network drivers. The header files in this section are included in the Windows Software Development Kit (SDK) instead of the Windows Driver Kit (WDK) as they are also shared with user mode networking applications.

ⓘ **Important**

This section's header topics contains pages for definitions, OIDs, status indications, and other data structures that are not part of network driver reference. Reference topics include structures, enumerations, functions, and callbacks.

For more information about network driver reference for these headers, see **Network driver reference in SDK header files**.

This section contains:

- Mstcpip.h
- Ntddndis.h
- Ws2def.h

Mstcpip.h

Article • 12/15/2021

This section contains kernel mode network driver topics for the Mstcpip.h header. This header is included in the Windows SDK as it is also shared with user mode networking applications.

The Mstcpip.h header contains definitions for Microsoft-specific extensions to the core Winsock definitions.

In this section

- SIO_LOOPBACK_FAST_PATH control code
- SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT control code
- SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS control code
- SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS control code

SIO_LOOPBACK_FAST_PATH control code

Article • 03/03/2023

Important The **SIO_LOOPBACK_FAST_PATH** is deprecated and is not recommended to be used in your code.

The **SIO_LOOPBACK_FAST_PATH** socket I/O control code allows a WSK application to configure a TCP socket for faster operations on the loopback interface.

To use this IOCTL, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	**SIO_LOOPBACK_FAST_PATH**
Level	0
InputSize	The size, in bytes, of the input buffer.
InputBuffer	A pointer to the input buffer. This parameter contains a pointer to a **Boolean** value that indicates if the socket should be configured for fast loopback operations.
OutputSize	0
OutputBuffer	**NULL**
OutputSizeReturned	**NULL**
Irp	A pointer to an IRP.

An application can use the **SIO_LOOPBACK_FAST_PATH** IOCTL to improve the performance of loopback operations on a TCP socket. This IOCTL requests that the TCP/IP stack use a special fast path for loopback operations on this socket. The **SIO_LOOPBACK_FAST_PATH** IOCTL can be used only with TCP sockets. This IOCTL must be used on both sides of the loopback session. The TCP loopback fast path is supported using either the IPv4 or IPv6 loopback interface.

The socket that plans to initiate the connection request must apply this IOCTL before making the connection request. The socket that is listening for the connection request must apply this IOCTL before accepting the connection.

Once an application establishes the connection on a loopback interface using the fast path, all packets for the lifetime of the connection must use the fast path.

Applying **SIO_LOOPBACK_FAST_PATH** to a socket which will be connected to a non-loopback path will have no effect.

This TCP loopback optimization results in packets that flow through Transport Layer (TL) instead of the traditional loopback through Network Layer. This optimization improves the latency for loopback packets. Once an applications opts in for a connection level setting to use the loopback fast path, all packets will follow the loopback path. For loopback communications, congestion and packet drop are not expected. The notion of congestion control and reliable delivery in TCP will be unnecessary. This, however, is not true for flow control. Without flow control, the sender can overwhelm the receive buffer, leading to erroneous TCP loopback behavior. The flow control in the TCP optimized loopback path is maintained by placing send requests in a queue. When the receive buffer is full, the TCP/IP stack guarantees that the sends won't complete until the queue is serviced, maintaining flow control.

TCP fast path loopback connections in the presence of a Windows Filtering Platform (WFP) callout for connection data must take the unoptimized slow path for loopback. So WFP filters will prevent this new loopback fast path from being used. When a WFP filter is enabled, the system will use the slow path even if the **SIO_LOOPBACK_FAST_PATH** IOCTL was set. This ensues that user-mode applications have the full WFP security capability.

By default, **SIO_LOOPBACK_FAST_PATH** is disabled.

Only a subset of the TCP/IP socket options are supported when the **SIO_LOOPBACK_FAST_PATH** IOCTL is used to enable the loopback fast path on a socket. The list of supported options includes the following:

- IP_TTL
- IP_UNICAST_IF
- IPV6_UNICAST_HOPS
- IPV6_UNICAST_IF
- IPV6_V6ONLY
- **SO_CONDITIONAL_ACCEPT**
- SO_EXCLUSIVEADDRUSE
- **SO_PORT_SCALABILITY**
- SO_RCVBUF
- SO_REUSEADDR

- TCP_BSDURGENT

A WSK application must specify a pointer to an IRP and a completion routine when calling the **WskControlSocket** function for this type of request. The application must not release the buffer till the WSK subsystem has completed the IRP. When it completes the IRP, the subsystem invokes the completion routine. In the completion routine, the application must check the IRP status and release all resources that it had previously allocated for the request.

For more information about WSK IRP handling, see Using IRPs with Winsock Kernel Functions.

When completing the IRP, the subsystem will set *Irp->IoStatus.Status* to **STATUS_SUCCESS** if the request is successful. Otherwise, *Irp->IoStatus.Status* will be set to **STATUS_INVALID_BUFFER_SIZE** or **STATUS_NOT_SUPPORTED** if the call is not successful.

Using IRPs with Winsock Kernel Functions

SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT control code

Article • 03/03/2023

The **SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT** socket I/O control operation allows a Winsock client to retrieve the redirect context for a redirect record for a redirected connection.

A WFP redirect record is a buffer of opaque data that WFP must set on an outbound proxy connection so that the redirected connection and the original connection are logically related.

Note The SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS query can only be used if the connection was redirected at the **FWPS_LAYER_ALE_CONNECT_REDIRECT_V4** or **FWPS_LAYER_ALE_CONNECT_REDIRECT_V6** layer by a WFP client.

For more information about redirection, see Using Bind or Connect Redirection.

To query the redirect context for a redirect record, a Winsock client calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	**SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT**
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	The size, in bytes, of the buffer that is pointed to by the *OutputBuffer* parameter.
OutputBuffer	A pointer to the buffer that receives the redirect context for the redirect record for the accepted TCP connection. The size of the buffer is specified in the *OutputSize* parameter.
OutputSizeReturned	A pointer to a **ULONG**-typed variable that receives the number of bytes of data that is copied into the buffer that is pointed to by the *OutputBuffer* parameter.

Parameter	Value
Irp	A pointer to an IRP.

The caller can perform this query in either of the following ways:

- It can set the *OutputBuffer* to a large buffer approximately 1 KB in size. If the output buffer size is not large enough, WskControlSocket will return **STATUS_BUFFER_TOO_SMALL** and *OutputSizeReturned* will contain the required size of the buffer. A larger buffer can then be allocated and **WskControlSocket** called again with the **SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT** request and *OutputBuffer* set to the larger buffer.
- Or it can set the *OutputSize* parameter to 0 and the *OutputBuffer* to NULL and then call WskControlSocket. Upon completion, the **WskControlSocket** function retrieves the output buffer size, in bytes, in the *OutputSizeReturned* parameter. An appropriately sized buffer can then be allocated and **WskControlSocket** called again with the **SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT** request and *OutputBuffer* set to the buffer.

Note It is also possible to perform this query in a user-mode application by using SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT (SDK).

For this type of request, the Winsock client must specify a pointer to an IRP and a pointer to its completion routine. The IRP can be passed to the client by a higher driver or the client can choose to allocate the IRP. To specify the completion routine, the client must call IoSetCompletionRoutine. For more details, see Using IRPs with Winsock Kernel Functions.

The Winsock client must not free the allocated buffer till the IRP is completed by WSK subsystem. When the WSK subsystem completes the IRP, it notifies the client by invoking the completion routine. A reference to that buffer is passed to the client by the WSK subsystem in the *Context* parameter of the completion routine. The size of the buffer is stored in *Irp->IoStatus.Information*.

The client can get the status of the IRP by checking *Irp->IoStatus.Status*. *Irp->IoStatus.Status* will be set to **STATUS_SUCCESS** if the request is successful. Otherwise, it will contain **STATUS_INTEGER_OVERFLOW**, **STATUS_NOT_FOUND**, **STATUS_BUFFER_TOO_SMALL**, or **STATUS_ACCESS_DENIED** if the call is not successful.

SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS

SIO_QUERY_WFP_CONNECTION_REDIRECT_CONTEXT (SDK)

SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS control code

Article • 03/03/2023

The **SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS** socket I/O control operation allows a Winsock client to retrieve the redirect record for a redirected connection.

A WFP redirect record is a buffer of opaque data that WFP must set on an outbound proxy connection so that the redirected connection and the original connection are logically related.

Note The **SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS** query can only be used if the connection was redirected at the **FWPS_LAYER_ALE_CONNECT_REDIRECT_V4** or **FWPS_LAYER_ALE_CONNECT_REDIRECT_V6** layer by a WFP client.

For more information about redirection, see Using Bind or Connect Redirection.

To query the redirect record for the redirected connection, a Winsock client calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	**SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS**
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	The size, in bytes, of the buffer that is pointed to by the *OutputBuffer* parameter.
OutputBuffer	A pointer to the buffer that receives the redirect record for the accepted TCP connection. The size of the buffer is specified in the *OutputSize* parameter.
OutputSizeReturned	A pointer to a **ULONG**-typed variable that receives the number of bytes of data that is copied into the buffer that is pointed to by the *OutputBuffer* parameter.
Irp	A pointer to an IRP.

The caller can perform this query in either of the following ways:

- It can set the *OutputBuffer* to a large buffer approximately 1 KB in size. If the output buffer size is not large enough, **WskControlSocket** will return a **STATUS_BUFFER_TOO_SMALL** and *OutputSizeReturned* will contain the required size of the buffer. A larger buffer can then be allocated and **WskControlSocket** called again with the **SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS** request and *OutputBuffer* set to the larger buffer.
- Or it can set the *OutputSize* parameter to 0 and the *OutputBuffer* to NULL and then call **WskControlSocket**. Upon completion, the **WskControlSocket** function retrieves the output buffer size, in bytes, in the *OutputSizeReturned* parameter. An appropriately sized buffer can then be allocated and **WskControlSocket** called again with the **SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS** request and *OutputBuffer* set to the buffer.

Note It is also possible to perform this query in a user-mode application by using SIO_QUERY_WFP_CONNECTION_REDIRECT_RECORDS (SDK).

For this type of request, the Winsock client must specify a pointer to an IRP and a pointer to its completion routine. The IRP can be passed to the client by a higher driver or the client can choose to allocate the IRP. To specify the completion routine, the client must call **IoSetCompletionRoutine**. For more details, see Using IRPs with Winsock Kernel Functions.

The Winsock client must not free the allocated buffer till the IRP is completed by WSK subsystem. When the WSK subsystem completes the IRP, it notifies the client by invoking the completion routine. A reference to that buffer is passed to the client by the WSK subsystem in the *Context* parameter of the completion routine. The size of the buffer is stored in *Irp->IoStatus.Information*.

The client can get the status of the IRP by checking *Irp->IoStatus.Status*. *Irp->IoStatus.Status* will be set to **STATUS_SUCCESS** if the request is successful. Otherwise, it will contain **STATUS_INTEGER_OVERFLOW**, **STATUS_NOT_FOUND**, **STATUS_BUFFER_TOO_SMALL**, or **STATUS_ACCESS_DENIED** if the call is not successful.

SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS control code

Article • 03/03/2023

The **SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS** socket I/O control operation allows a Winsock client to specify the redirect record to the new TCP socket used for connecting to the final destination.

A WFP redirect record is a buffer of opaque data that WFP must set on an outbound proxy connection so that the redirected connection and the original connection are logically related.

For more information about redirection, see Using Bind or Connect Redirection.

To set the redirect record to the new TCP socket used for connecting to the final destination, a Winsock client calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	**SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS**
Level	0
InputSize	The size of the redirect record pointed to by the InputBuffer parameter.
InputBuffer	A pointer to the redirect record associated with the socket.
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL
Irp	A pointer to an IRP.

The Winsock client must allocate a buffer and specify a pointer to the buffer and its size in *InputBuffer* and *InputSize*.

A Winsock client must specify a pointer to an IRP and a completion routine when calling the **WskControlSocket** function for this type of request. The client must not release the buffer till the WSK subsystem has completed the IRP. When it completes the IRP, the subsystem invokes the completion routine. In the completion routine, the client must check the IRP status and release all resources that it had previously allocated for the request.

Note It is also possible to perform this query in a user-mode application by using SIO_SET_WFP_CONNECTION_REDIRECT_RECORDS (SDK).

For more information about WSK IRP handling, see Using IRPs with Winsock Kernel Functions.

The client can get the status of the IRP by checking *Irp->IoStatus.Status*. *Irp->IoStatus.Status* will be set to **STATUS_SUCCESS** if the request is successful. Otherwise, it will contain **STATUS_INTEGER_OVERFLOW**, or **STATUS_ACCESS_DENIED** if the call is not successful.

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Header	Mstcpip.h
IRQL	PASSIVE_LEVEL

ⓘ Important

Bias-free communication

Microsoft supports a diverse and inclusive environment. This article contains references to terminology that the Microsoft **style guide for bias-free communication** recognizes as exclusionary. The word or phrase is used in this article for consistency because it currently appears in the software. When the software is updated to remove the language, this article will be updated to be in alignment.

This section contains kernel mode network driver topics for the Ntddndis.h header. This header is included in the Windows SDK as it is also shared with user mode networking applications.

The Ntddndis.h header contains definitions for constants and types for interfacing with network drivers.

ⓘ Note

This section's topics contains pages for definitions and OIDs, which are not part of network driver DDI reference.

For DDI reference for this header, see **ntddndis.h header**.

GUID_NDIS_GEN_PCI_DEVICE_CUSTOM_PROPERTIES

Article • 03/14/2023

WMI clients can use the GUID_NDIS_GEN_PCI_DEVICE_CUSTOM_PROPERTIES method GUID to determine the current link state.

Remarks

NDIS handles this GUID and miniport drivers do not receive an OID query.

When a WMI client issues a GUID_NDIS_GEN_PCI_DEVICE_CUSTOM_PROPERTIES WMI method request, NDIS returns the PCI custom properties of a PCI device for the miniport adapter. The WMI method identifier should be NDIS_WMI_DEFAULT_METHOD_ID, and the WMI input buffer should contain an NDIS_WMI_METHOD_HEADER structure.

The data buffer that NDIS returns with this GUID contains an NDIS_PCI_DEVICE_CUSTOM_PROPERTIES structure.

Requirements

Version	Supported in NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_PCI_DEVICE_CUSTOM_PROPERTIES

NDIS_WMI_METHOD_HEADER

OID_802_3_ADD_MULTICAST_ADDRESS

Article • 02/18/2023

As a set request, NDIS and overlying protocol drivers use the OID_802_3_ADD_MULTICAST_ADDRESS OID request to add an 802.3 multicast address to the multicast address list of a miniport adapter. The multicast address is an array of 6 bytes. Adding an address enables that address to receive multicast packets.

Version Information

Windows Vista
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

Remarks

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the 6-byte address to be added to the multicast address list.

The OID_802_3_ADD_MULTICAST_ADDRESS OID request can add only one address. To add more than one address, the overlying driver must issue multiple OID_802_3_ADD_MULTICAST_ADDRESS OID requests.

NDIS miniport drivers do not receive this OID request directly. Instead, NDIS consolidates each sequence of OID_802_3_ADD_MULTICAST_ADDRESS and OID_802_3_DELETE_MULTICAST_ADDRESS OID requests into a single OID_802_3_MULTICAST_LIST OID request, which it sends to the miniport driver.

To receive multicast packets, the overlying driver must use the OID_GEN_CURRENT_PACKET_FILTER OID to set the packet filter **NDIS_PACKET_TYPE_MULTICAST** flag.

The miniport driver can set a limit on the number of multicast addresses that the multicast address list can contain. To specify the maximum number of multicast addresses, the miniport driver sets the **MaxMulticastListSize** member of the **NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES** structure that it passes to the **NdisMSetMiniportAttributes** function. For miniport drivers that are based on NDIS versions before NDIS 6.0, NDIS queries the maximum number of multicast addresses by sending an OID_802_3_MAXIMUM_LIST_SIZE OID request. NDIS returns

NDIS_STATUS_MULTICAST_FULL if an OID_802_3_ADD_MULTICAST_ADDRESS request exceeds this limit.

To delete a previously added multicast address, make a set request with the OID_802_3_DELETE_MULTICAST_ADDRESS OID. The overlying driver can add a given multicast address multiple times. If NDIS succeeds the first add request for a given multicast address, NDIS will succeed all subsequent add requests for that address. To delete a multicast address that was added more than once, the overlying driver must delete the address the same number of times that it added the address.

Requirements

Article • 02/18/2023

The address the NIC is currently using.

The network management software cannot set the current station address using the NDIS interface library. It must set this address as a configuration parameter.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_802_3_DELETE_MULTICAST_ADDRESS

Article • 02/18/2023

As a set request, NDIS and overlying protocol drivers use the OID_802_3_DELETE_MULTICAST_ADDRESS OID to delete a previously added multicast address from the multicast address list of a miniport adapter. The multicast address is an array of 6 bytes. Deleting an address disables that address so that it can no longer receive multicast packets.

Version Information

Windows Vista
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

Remarks

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the 6-byte address to be deleted from the multicast address list.

The OID_802_3_DELETE_MULTICAST_ADDRESS OID request can delete only one address. To delete more than one address, the protocol driver must issue multiple OID_802_3_DELETE_MULTICAST_ADDRESS OID requests.

NDIS miniport drivers do not receive this OID request directly. Instead, NDIS consolidates each sequence of OID_802_3_ADD_MULTICAST_ADDRESS and OID_802_3_DELETE_MULTICAST_ADDRESS OID requests into a single OID_802_3_MULTICAST_LIST OID request.

To replace or delete the entire multicast list, the protocol driver can use the OID_802_3_MULTICAST_LIST OID request.

To add an address to the list, the protocol driver can use the OID_802_3_ADD_MULTICAST_ADDRESS OID request.

The overlying protocol driver can add a given multicast address multiple times by sending multiple OID_802_3_ADD_MULTICAST_ADDRESS OID requests. If NDIS succeeds the first add request for a given multicast address, NDIS will succeed all subsequent add requests for that address. To delete a multicast address that was added more than once, the overlying driver must delete the address the same number of times that it added the address.

Return status codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the **NdisMOidRequestComplete** function, passing NDIS_STATUS_SUCCESS for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_802_3_ADD_MULTICAST_ADDRESS

OID_802_3_MAXIMUM_LIST_SIZE

OID_802_3_MULTICAST_LIST

OID_802_3_MAC_OPTIONS

Article • 02/18/2023

A protocol can use this OID to determine features supported by the underlying driver, which could be emulating Ethernet.

The underlying driver returns zero, indicating that it supports no options.

Note This OID is obsolete for NDIS 6 drivers.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_802_3_MAXIMUM_LIST_SIZE

Article • 02/18/2023

NDIS and overlying protocol drivers use the OID_802_3_MAXIMUM_LIST_SIZE OID request to query or set the maximum number of 6-byte multicast addresses that the miniport adapter's multicast address list can hold.

This multicast address list is shared by all protocol drivers that are bound to the miniport adapter. Because it is a shared resource, a protocol driver can receive **NDIS_STATUS_MULTICAST_FULL** from the miniport adapter in response to an OID_802_3_MULTICAST_LIST OID set request, even if the number of elements in the list is less than the number that NDIS previously returned for an OID_802_3_MAXIMUM_LIST_SIZE OID query request.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_802_3_ADD_MULTICAST_ADDRESS

OID_802_3_DELETE_MULTICAST_ADDRESS

OID_802_3_MULTICAST_LIST

OID_802_3_MULTICAST_LIST

Article • 02/18/2023

As a set request, NDIS and overlying protocol drivers use the OID_802_3_MULTICAST_LIST OID request to replace the current multicast address list on a miniport adapter. If an address is present in the list, that address is enabled to receive multicast packets.

As a query request, NDIS and protocol drivers use the OID_802_3_MULTICAST_LIST OID request to obtain the current multicast address list.

NDIS handles OID_802_3_MULTICAST_LIST query requests for miniport drivers, so miniport drivers never receive these query requests.

Miniport drivers that support multicast address lists must support OID_802_3_MULTICAST_LIST set requests.

For a set request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the multicast address list as an array of addresses.

- Each address is an array of 6 bytes.
- The **InformationBufferLength** member contains the length, in bytes, of the **InformationBuffer** array.
- If there are duplicate addresses in the list in the **InformationBuffer** member, NDIS removes the duplicates before sending the OID_802_3_MULTICAST_LIST set request to the miniport driver.
- If the **InformationBufferLength** member is zero, the miniport driver must clear the multicast address list.
- If the **InformationBufferLength** member is greater than zero, the miniport driver must replace any existing multicast address list with the list in the **InformationBuffer** member.

The miniport adapter's multicast address list is shared by all protocol drivers that are bound to the miniport adapter. NDIS controls access to this list. If multiple protocol drivers try to modify the list at the same time, NDIS combines their requests into a single OID_802_3_MULTICAST_LIST set request, which it sends to the miniport driver.

When a miniport adapter is initialized, it resets the NIC so the multicast address list is zero. NDIS also initializes the packet filter so it does not allow the protocol driver to receive multicast packets.

To receive a multicast packet, the protocol driver must later do one of the following:

- Set the packet filter to include the **NDIS_PACKET_TYPE_MULTICAST** flag. At any time, it can disable multicast packet reception by canceling this flag. The order in which the protocol driver enables reception for multicast packets is not important. For more information, see the OID_GEN_CURRENT_PACKET_FILTER OID request.
- Set the packet filter to include the **NDIS_PACKET_TYPE_ALL_MULTICAST** flag, which enables all multicast packets, and do the filtering itself.

The miniport driver can set a limit on the number of multicast addresses that the multicast address list can contain. NDIS returns **NDIS_STATUS_MULTICAST_FULL** if a protocol driver exceeds this limit or if it specifies an invalid multicast address.

For a query request, NDIS returns a multicast address list that is the union of all multicast address lists for all protocol bindings.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_802_3_XMIT_TIMES_CRS_LOST

Article • 02/18/2023

The number of times the CRS signal has been lost during packet transmission.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_802_3_XMIT_UNDERRUN

Article • 02/18/2023

The number of frames not transmitted due to underrun errors on the NIC.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_ADD_ADDRESS

Article • 02/18/2023

The OID_CO_ADD_ADDRESS OID is sent by a client to a call manager to specify an alias address for a host. The alias address is formatted as a CO_ADDRESS structure, defined as follows:

C++

```
typedef struct _CO_ADDRESS{
    ULONG   AddressSize;
    UCHAR   Address[1];
} CO_ADDRESS, *PCO_ADDRESS;
```

The members of this structure contain the following information:

AddressSize
Specifies the size in bytes of the structure at **Address**.

Address
Specifies a variable-length array that contains the alias address. The address format is specific to the signaling protocol used by the call manager.

This OID is typically used to specify a well-known address at which a host offers a particular service. For example, a client could specify a well-known address for a LAN emulation server. The call manager's response to this OID is specific to the signaling protocol used by the call manager. An ATM call manager, for example, sends a message to the switch that notifies the switch of the alias address.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_ADD_PVC

Article • 02/18/2023

The OID_CO_ADD_PVC OID is sent by a client to a call manager to add a permanent virtual connection (PVC) to the call manager's list of configured PVCs. The PVC is formatted as a CO_PVC structure, defined as follows:

C++

```
typedef struct _CO_PVC {
    NDIS_HANDLE             NdisAfHandle;
    CO_SPECIFIC_PARAMETERS  PvcParameters;
} CO_PVC, *PCO_PVC;
```

The members of this structure contain the following information:

NdisAfHandle
Specifies the NDIS-supplied handle returned by NdisClOpenAddressFamilyEx.

PvcParameters
A formatted CO_SPECIFIC_PARAMETERS structure. This structure contains protocol-specific parameters that describe the PVC.

A PVC is configured manually by an administrator. A client that monitors such activity notifies a call manager of a newly configured PVC by sending this OID to the call manager. Other clients can then use the newly-configured PVC.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_ADDRESS_CHANGE

Article • 02/18/2023

The OID_CO_ADDRESS_CHANGE OID is sent by the call manager to each client that opened an address family with the call manager. This action is taken in response to a change in the switch address that the call manager uses. For example, the call manager sends this request if someone disconnects the NIC from one switch and plugs it into another switch. Each notified client must send an OID_CO_GET_ADDRESSES query to the call manager to retrieve a list of currently valid addresses.

The call manager also sends OID_CO_ADDRESS_CHANGE to a client immediately after the client opens an address family with the call manager. This ensures that a client that opens an address family after the switch address has changed is notified of the change. The client must then must then send an OID_CO_GET_ADDRESSES query to the call manager.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_AF_CLOSE

Article • 02/18/2023

The OID_CO_AF_CLOSE OID is sent by a call manager that must unbind itself from an underlying miniport driver. Before unbinding itself from the miniport driver, the call manager sends this OID to each client that has an address family open with the call manager. In response, the client should do the following:

1. If the client has any active multipoint connections, call NdisClDropParty as many times as necessary until only a single party remains active on each multipoint VC
2. Call NdisClCloseCall as many times as necessary to close all calls still open with the call manager
3. Call NdisClDeregisterSap as many times as necessary to deregister all SAPs that the client has registered with the call manager
4. Call NdisClCloseAddressFamily to close the address family referenced by NdisAfHandle in the request that contained OID_CO_AF_CLOSE

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_DELETE_ADDRESS

Article • 02/18/2023

The OID_CO_DELETE_ADDRESS OID is sent by a client to a call manager to delete an alias address for a host. The alias address is formatted as a CO_ADDRESS structure, defined as follows:

```c++
typedef struct _CO_ADDRESS {
    ULONG   AddressSize;
    UCHAR   Address[1];
} CO_ADDRESS, *PCO_ADDRESS;
```

The members of this structure contain the following information:

AddressSize
Specifies the size in bytes of the structure at Address .

Address
Specifies a variable-length array that contains the alias address. The address format is specific to the signaling protocol used by the call manager.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_DELETE_PVC

Article • 02/18/2023

The OID_CO_DELETE_PVC OID is sent by a client to a call manager to delete a permanent virtual connection (PVC) from the call manager's list of configured PVCs. The PVC is formatted as a CO_PVC structure, defined as follows:

```c++
typedef struct _CO_PVC {
    NDIS_HANDLE             NdisAfHandle;
    CO_SPECIFIC_PARAMETERS  PvcParameters;
} CO_PVC, *PCO_PVC;
```

The members of this structure contain the following information:

NdisAfHandle
Specifies the NDIS-supplied handle returned by NdisClOpenAddressFamilyEx.

PvcParameters
A formatted CO_SPECIFIC_PARAMETERS structure. This structure contains protocol-specific parameters that describe the PVC.

A PVC is removed manually by an administrator. A client that monitors such activity notifies a call manager of a PVC that has been removed by sending this OID to the call manager.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_GET_ADDRESSES

Article • 02/18/2023

The OID_CO_GET_ADDRESSES OID is used by the client to make a query to the call manager. This query is made in response to the call manager sending an OID_CO_ADDRESS_CHANGE to the client. In response to this query, the call manager sends the client an address list that is formatted as a CO_ADDRESS_LIST structure, defined as follows:

```c++
typedef struct _CO_ADDRESS_LIST {
    ULONG       NumberOfAddressesAvailable;
    ULONG       NumberOfAddresses;
    CO_ADDRESS  AddressList;
} CO_ADDRESS_LIST, *PCO_ADDRESS_LIST;
```

The members of this structure contain the following information:

NumberOfAddressesAvailable
Specifies the maximum number of addresses in the call manager's list of addresses. Regardless of the actual number of addresses that the call manager returns to the client at **AddressList**, the size of the buffer at **AddressList** is always **NumberOfAddressesAvailable** multiplied by the address size, which is a fixed size specific to the call manager.

NumberOfAddresses
Specifies the number of addresses that the call manager has written to **AddressList**.

AddressList
The alias address is formatted as a CO_ADDRESS structure, defined as follows:

```c++
typedef struct _CO_ADDRESS {
    ULONG   AddressSize;
    UCHAR   Address[1];
} CO_ADDRESS, *PCO_ADDRESS;
```

The members of this structure contain the following information:

AddressSize
Specifies the size in bytes of the structure at **Address** .

Address
Specifies a variable-length array that contains the list of addresses. The address format is specific to the signaling protocol used by the call manager.

The **AddressList** contains network addresses at which the local host can be reached. The **AddressList** returned to a particular client contains addresses that are common to all clients, as well as any addresses that the client itself has added to call manager's list of addresses with OID_CO_ADD_ADDRESS.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_GET_CALL_INFORMATION

Article • 02/18/2023

The OID_CO_GET_CALL_INFORMATION OID is reserved for future use.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_SIGNALING_DISABLED

Article • 02/18/2023

The OID_CO_SIGNALING_DISABLED OID is sent by a call manager to indicate that it cannot make calls or dispatch incoming calls. The call manager sends this OID to each client that has an address family open with the call manager.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_SIGNALING_ENABLED

Article • 02/18/2023

The OID_CO_SIGNALING_ENABLED OID is sent by a call manager to indicate that it is ready to make calls and dispatch incoming calls. The call manager sends this OID to each client that has an address family open with the call manager.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_ADDRESS_CAPS

Article • 02/18/2023

The OID_CO_TAPI_ADDRESS_CAPS OID requests a call manager or an integrated miniport call manager (MCM) driver to return the telephony capabilities for a specified address on a specified line.

This request uses a CO_TAPI_ADDRESS_CAPS structure, which is defined as follows:

```c++
typedef struct _CO_TAPI_ADDRESS_CAPS {
    IN  ULONG                ulLineID;
    IN  ULONG                ulAddressID;
    OUT ULONG                ulFlags;
    OUT LINE_ADDRESS_CAPS    LineAddressCaps;
} CO_TAPI_ADDRESS_CAPS, *PCO_TAPI_ADDRESS_CAPS;
```

The members of this structure contain the following information:

ulLineID
Specifies the zero-based line identifier of the line on which the given address is located.

ulAddressID
Specifies the zero-based address identifier on the line for which capabilities should be returned.

ulFlags
These flags are reserved.

LineAddressCaps
Specifies the telephony capabilities of an address, formatted as a LINE_ADDRESS_CAPS structure. For more information about this structure, see the Microsoft Windows SDK and the ndistapi.h header file.

Remarks

After querying the line capabilities of a call manager's or MCM driver's device with OID_CO_TAPI_LINE_CAPS, a connection-oriented client queries the capabilities of the address(es) for each line as follows:

- If the previous query of OID_CO_TAPI_LINE_CAPS indicated that the line supports only one address or that all addresses on the line have the same address capabilities, the client queries OID_CO_TAPI_ADDRESS_CAPS once to determine the capabilities of all the addresses on the line. In this case, the address capabilities returned by the call manager or MCM driver apply to all addresses on the line.

- If a line supports multiple addresses that have dissimilar capabilities, the client queries OID_CO_TAPI_ADDRESS_CAPS once for each address on the line. In this case, the address capabilities returned by the call manager or MCM driver apply to a specified address on a specified line.

The call manager or MCM driver returns the address capabilities for a specified address in **LineAddressCaps**.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_CM_CAPS

Article • 02/18/2023

The OID_CO_TAPI_CM_CAPS OID requests a call manager or an integrated miniport call manager (MCM) driver to return the number of lines supported by its device (the device for which it provides call management services). This OID also requests the call manager or MCM driver to indicate whether these lines have dissimilar line capabilities.

This request uses a CO_TAPI_CM_CAPS structure, which is defined as follows:

```C++
typedef struct _CO_TAPI_CM_CAPS {
    OUT ULONG   ulCoTapiVersion;
    OUT ULONG   ulNumLines;
    OUT ULONG   ulFlags;
} CO_TAPI_CM_CAPS, *PCO_TAPI_CM_CAPS;
```

The members of this structure contain the following information:

ulCoTapiVersion

Specifies the TAPI version supported by the call manager or MCM driver. The call manager or MCM driver should set this to CO_TAPI_VERSION.

ulNumLines

Specifies the number of lines supported by the device.

ulFlags

If the device supports multiple lines that have dissimilar line capabilities or if the addresses on any of these lines have dissimilar address capabilities, the call manager or MCM driver sets the CO_TAPI_FLAG_PER_LINE_CAPS bit in **ulFlags**; otherwise, the call manager or MCM driver clears this bit. All undefined bits are reserved for future use and must be set to 0.

Remarks

A connection-oriented client uses the information returned from this OID to determine how it will query the line capabilities of the call manager's or MCM driver's device with OID_CO_TAPI_LINE_CAPS.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_GET_CALL_DIAGNOSTICS

Article • 02/18/2023

The OID_CO_TAPI_GET_CALL_DIAGNOSTICS OID requests a call manager or MCM driver to return diagnostic information about a failed call or a call torn down by the remote TAPI party.

This request uses a CO_TAPI_CALL_DIAGNOSTICS structure, which is defined as follows:

```C++
typedef struct _CO_TAPI_CALL_DIAGNOSTICS {
    OUT ULONG                   ulOrigin;
    OUT ULONG                   ulReason;
    OUT NDIS_VAR_DATA_DESC  DiagInfo;
} CO_TAPI_CALL_DIAGNOSTICS, *PCO_TAPI_CALL_DIAGNOSTICS;
```

ulOrigin
Specifies the origination of the call as one of the following LINECALLORIGIN_ constants:

- **LINECALLORIGIN_OUTBOUND**
  The call is an outgoing call.

- **LINECALLORIGIN_INTERNAL**
  The call is incoming and originated internally (on the same PBX, for example).

- **LINECALLORIGIN_EXTERNAL** The call is incoming and originated externally.

- **LINECALLORIGIN_UNKNOWN**
  The call is incoming. Its origin is currently unknown but may become known later.

- **LINECALLORIGIN_UNAVAIL**
  The call is incoming. Its origin is not available and will never be known.

- **LINECALLORIGIN_CONFERENCE**
  The call handle is for a conference call--that is, for the application's connection to the conference bridge in the switch.

ulReason
Specifies the reason for the call as one of the following LINECALLREASON_ constants:

- **LINECALLREASON_DIRECT**
  The call is direct.

- LINECALLREASON_FWDBUSY

  The call was forwarded from a busy extension.

- LINECALLREASON_FWDNOANSWER

  The call was forwarded after some number of rings from an unanswered extension.

- LINECALLREASON_FWDUNCOND

  The call was forwarded unconditionally from another number.

- LINECALLREASON_PICKUP

  The call was picked up from another extension.

- LINECALLREASON_UNPARK

  The call was retrieved as a parked call.

- LINECALLREASON_REDIRECT

  The call was redirected to this station.

- LINECALLREASON_CALLCOMPLETION

  The call was the result of a call completion request.

- LINECALLREASON_TRANSFER

  The call was transferred from another number. Party identifier information may indicate who the caller is and from where the call was transferred.

- LINECALLREASON_REMINDER

  The call is a reminder (or "recall") that the user has a call parked or on hold for a potentially long time.

- LINECALLREASON_UNKNOWN

  The reason for the call is currently unknown but may become known later.

- LINECALLREASON_UNAVAIL

  The reason for the call is unavailable and cannot become known later.

DiagInfo

Specifies an NDIS_VAR_DATA_DESC structure that contains an offset to, as well as the length of, optional diagnostic information supplied by the call manager or MCM driver. The content and format of the diagnostic information is driver-determined.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_LINE_CAPS

Article • 02/18/2023

The OID_CO_TAPI_LINE_CAPS OID requests a call manager or an integrated miniport call manager (MCM) driver to return the telephony capabilities for a specified line. This OID also requests the call manager or MCM driver to indicate whether addresses on this line have dissimilar telephony capabilities.

This request uses a CO_TAPI_LINE_CAPS structure, defined as follows, to query the telephony capabilities of a specified line:

```c++
typedef struct _CO_TAPI_LINE_CAPS {
    IN  ULONG           ulLineID;
    OUT ULONG           ulFlags;
    OUT LINE_DEV_CAPS   LineDevCaps;
} CO_TAPI_LINE_CAPS, *PCO_TAPI_LINE_CAPS;
```

The members of this structure contain the following information:

ulLineID
Specifies the line for which telephony capabilities should be returned. **ulLineID** is a zero-based identifier.

ulFlags
If the line supports multiple addresses that have dissimilar telephony capabilities, the call manager or MCM driver sets the CO_TAPI_FLAG_PER_ADDRESS_CAPS bit in ulFlags; otherwise, the call manager or MCM driver clears this bit. All undefined bits are reserved and must be set to 0.

LineDevCaps
Specifies the telephony capabilities of a line, formatted as a LINE_DEV_CAPS structure. For more information about this structure, see the Microsoft Windows SDK and the ndistapi.h header file.

Remarks

After querying the telephony capabilities of a call manager's or MCM driver's device with OID_CO_TAPI_CM_CAPS, a connection-oriented client queries the telephony capabilities of the line(s) supported by the device.

- If all lines supported by the device have the same line capabilities and all the addresses on these lines have the same address capabilities, the client queries OID_CO_TAPI_LINE_CAPS once to obtain the line capabilities of the device. In this case, the line capabilities returned by the call manager or MCM driver apply to all the lines supported by the device.
- If the device supports multiple lines with dissimilar capabilities, however, and/or if addresses on these lines have dissimilar address capabilities, the client queries OID_CO_TAPI_LINE_CAPS once for each line supported by the device to obtain the capabilities of each line.

The **ulFlags** setting determines how many times the client subsequently queries the capabilities of the address(es) on the line:

- If the line supports only one address, or if the line supports multiple addresses that have the same address capabilities, the client queries OID_CO_TAPI_ADDRESS_CAPS once.
- If the line supports multiple addresses that have dissimilar capabilities, the client must query OID_CO_TAPI_ADDRESS_CAPS once for each address on the line.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_TRANSLATE_NDIS_CALLPARAMS

Article • 03/14/2023

The OID_CO_TAPI_TRANSLATE_NDIS_CALLPARAMS OID requests a call manager or MCM driver to translate NDIS call parameters (passed in a CO_CALL_PARAMETERS structure to the client's ProtocolClIncomingCall function) to TAPI call parameters. The client uses the translated TAPI call parameters returned by the call manager or MCM driver to determine whether to accept or reject the incoming call.

This request uses a CO_TAPI_TRANSLATE_NDIS_CALLPARAMS structure, which is defined as follows:

```C++
typedef struct _CO_TAPI_TRANSLATE_NDIS_CALLPARAMS {
    IN  ULONG               ulFlags;
    IN  NDIS_VAR_DATA_DESC  NdisCallParams;
    OUT NDIS_VAR_DATA_DESC  LineCallInfo;
} CO_TAPI_TRANSLATE_NDIS_CALLPARAMS, *PCO_TAPI_TRANSLATE_NDIS_CALLPARAMS;
```

The members of this structure contain the following information:

ulFlags
The client must set the CO_TAPI_FLAG_INCOMING_CALL bit in **ulFlags**.

NdisCallParams
Specifies an NDIS_VAR_DATA_DESC structure that contains an offset from the beginning of the NDIS_VAR_DATA_DESC structure to a CO_CALL_PARAMETERS structure. The NDIS_VAR_DATA_DESC structure also contains the length of the CO_CALL_PARAMETERS structure. The client fills in the CO_CALL_PARAMETERS structure with the NDIS call parameters to be translated to TAPI call parameters.

LineCallInfo
Specifies an NDIS_VAR_DATA_DESC structure that contains an offset from the beginning of the NDIS_VAR_DATA_DESC structure to a LINE_CALL_INFO structure. The NDIS_VAR_DATA_DESC structure also contains the length of the CO_CALL_PARAMETERS structure. The LINE_CALL_INFO structure specifies the TAPI call parameters into which the given NDIS call parameters have been translated. For more information about the LINE_CALL_INFO structure, see the Windows SDK and the ndistapi.h header file.

Remarks

If the request is successful, the call manager or MCM driver fills in the LINE_CALL_PARAMS structure referred to by **LineCallInfo** with the translated TAPI call parameters. The call manager or MCM driver must allocate the LINE_CALL_INFO structure within the flat memory section referred to **LineCallInfo**. The client writes the total length of the LINE_CALL_INFO structure to **LineCallInfo.Length**.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_TRANSLATE_TAPI_CALLPARAMS

Article • 02/18/2023

The OID_CO_TAPI_TRANSLATE_TAPI_CALLPARAMS OID requests a call manager or integrated call manager miniport (MCM) driver to translate TAPI call parameters to NDIS call parameters. The client that queries this OID uses the returned NDIS call parameters as an input (formatted as a CO_CALL_PARAMETERS structure) to NdisClMakeCall, with which the client places an outgoing call.

This OID uses a CO_TAPI_TRANSLATE_TAPI_CALLPARAMS structure, which is defined as follows:

C++

```
typedef struct _CO_TAPI_TRANSLATE_TAPI_CALLPARAMS {
    IN  ULONG                   ulLineID;
    IN  ULONG                   ulAddressID;
    IN  ULONG                   ulFlags;
    IN  NDIS_VAR_DATA_DESC   DestAddress;
    IN  NDIS_VAR_DATA_DESC   LineCallParams;
    OUT NDIS_VAR_DATA_DESC   NdisCallParams;
} CO_TAPI_TRANSLATE_TAPI_CALLPARAMS, *PCO_TAPI_TRANSLATE_TAPI_CALLPARAMS;
```

The members of this structure contain the following information:

ulLineID

Specifies a zero-based line identifier to which the outgoing call will be directed.

ulAddressID

Specifies a zero-based address identifier (on the line specified by **ulLineID**) to which the outgoing call will be directed.

ulFlags

The client must set the CO_TAPI_FLAG_OUTGOING_CALL bit in **ulFlags**. The client can optionally set the CO_TAPI_USE_DEFAULT_CALLPARAMS bit in **ulFlags** to require the call manager or MCM driver to ignore the **LineCallParams** and return the default NDIS call parameters for the device.

DestAddress

Specifies an NDIS_VAR_DATA_DESC structure that contains an offset from the beginning of the NDIS_VAR_DATA_DESC structure to a destination address formatted as a character array. The NDIS_VAR_DATA_DESC structure also contains the length of the destination address. The destination address is the address to which the outgoing call will be directed.

LineCallParams
Specifies an NDIS_VAR_DATA_DESC structure that contains an offset from the beginning of the NDIS_VAR_DATA_DESC structure to a LINE_CALL_PARAMS structure. The NDIS_VAR_DATA_DESC structure also contains the length of the LINE_CALL_PARAMS structure. The LINE_CALL_PARAMS structure specifies the TAPI call parameters to be translated into NDIS call parameters. For more information about the LINE_CALL_PARAMS structure, see the Microsoft Windows SDK and the ndistapi.h header file.

NdisCallParams
Specifies an NDIS_VAR_DATA_DESC structure that contains an offset from the beginning of the NDIS_VAR_DATA_DESC structure to a CO_CALL_PARAMETERS structure. The NDIS_VAR_DATA_DESC structure also contains the length of the CO_CALL_PARAMETERS structure. The CO_CALL_PARAMETERS structure specifies the NDIS call parameters into which the given TAPI call parameters have been translated.

Remarks

If the request is successful, the call manager or MCM driver fills in the CO_CALL_PARAMETERS structure referenced by **NdisCallParams** with the translated NDIS call parameters. The call manager or MCM driver must allocate the CO_CALL_PARAMETERS structure within the flat memory section referred to by **NdisCallParams**. The client writes the total length of the CO_CALL_PARAMETERS structure to **NdisCallParams.Length**.

If the client sets the CO_TAPI_USE_DEFAULT_CALLPARAMS bit in **ulFlags**, the client does not specify TAPI call parameters. In this case, the call manager or MCM driver should return the default NDIS call parameters for the device. If there are no default NDIS call parameters for the device, the call manager or MCM driver should return NDIS_STATUS_FAILURE.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_CO_TAPI_TRANSLATE_TAPI_SAP

Article • 02/18/2023

The OID_CO_TAPI_TRANSLATE_TAPI_SAP OID requests a call manager or integrated MCM driver to prepare one or more SAPs from TAPI call parameters. The client that queries this OID uses an NDIS SAP returned by the call manager or MCM driver as an input (formatted as a CO_SAP structure) to NdisClRegisterSap, which the client calls to register a SAP on which to receive incoming calls.

This request uses a CO_TAPI_TRANSLATE_SAP structure, which is defined as follows:

C++

```
typedef struct _CO_TAPI_TRANSLATE_SAP {
    IN  ULONG               ulLineID;
    IN  ULONG               ulAddressID;
    IN  ULONG               ulMediaModes;
    IN  ULONG               Reserved;
    OUT ULONG               NumberOfSaps;
    OUT NDIS_VAR_DATA_DESC  NdisSapParams[1];
} CO_AF_TAPI_SAP, *PCO_AF_TAPI_SAP;
```

The members of this structure contain the following information:

ulLineID

Specifies a zero-based line identifier.

ulAddressID

Specifies a zero-based address identifier on the line specified by **ulLineID**.

ulMediaModes

Specifies the media mode of the information stream of calls that the client is interested in, as one or more of the following LINEMEDIAMODE_constants:

- LINEMEDIAMODE_UNKNOWN
  A media stream exists but its mode is currently unknown and may become known later. This corresponds to a call with an unclassified media type. In typical analog telephony environments, the media mode of an incoming call may be unknown until after the call has been answered and the media stream has been filtered to make a determination.

  If the **LINEMEDIAMODE_UNKNOWN** flag is set, other media flags can also be set. This signifies that the media is unknown but that it is likely to be one of the other indicated media modes.

- LINEMEDIAMODE_INTERACTIVEVOICE
  The presence of voice energy on the call, and the call is treated as an interactive call with humans on both ends.

- LINEMEDIAMODE_AUTOMATEDVOICE
  The presence of voice energy on the call, and the voice is locally handled by an automated application.

- LINEMEDIAMODE_DATAMODEM
  A data modem session on the call.

- LINEMEDIAMODE_G3FAX
  A group 3 fax is being sent or received over the call.

- LINEMEDIAMODE_G4FAX
  A group 4 fax is being sent or received over the call.

- LINEMEDIAMODE_TDD
  A TDD (telecommunication device for the deaf) session on the call.

- LINEMEDIAMODE_DIGITALDATA
  Digital data is being sent or received over the call.

- LINEMEDIAMODE_TELETEX
  A teletex session on the call. (Teletex is one of the telematic services.)

- LINEMEDIAMODE_VIDEOTEX
  A videotex session on the call. (Videotex is one the telematic services.)

- LINEMEDIAMODE_TELEX
  A telex session on the call. (Telex is one of the telematic services.)

- LINEMEDIAMODE_MIXED
  A mixed session on the call. (Mixed is one of the ISDN telematic services.)

- LINEMEDIAMODE_ADSI
  An ADSI (Analog Display Service Interfaces) session on the call.

- LINEMEDIAMODE_VOICEVIEW
  The media mode of the call is VoiceView.

Reserved
This is reserved. The client must set this field to 0.

NumberOfSaps
Specifies the number of NDIS_VAR_DATA_DESC structures contained in the buffer at

NdisSapParams.

NdisSapParams
Specifies a variable-length array that contains one or more NDIS_VAR_DATA_DESC structures. Each NDIS_VAR_DATA_DESC structure contains an offset to, as well as the length of, a CO_SAP structure. Each CO_SAP structure specifies a service access point (SAP) on which a connection-oriented client can receive incoming calls.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_ADMIN_STATUS

Article • 02/18/2023

As a query, use the OID_GEN_ADMIN_STATUS OID to determine the administrative status for an interface (*ifAdminStatus* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

The administrative status is the status that the system administrator requested.

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the query succeeds, the interface provider returns NDIS_STATUS_SUCCESS, and the result of the query can be one of the values in the **NET_IF_ADMIN_STATUS** enumeration.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NET_IF_ADMIN_STATUS

NDIS Network Interface OIDs

OID_GEN_ALIAS

Article • 02/18/2023

As a query, use the OID_GEN_ALIAS OID to obtain the alias string for an interface (*ifAlias* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

An NDIS network interface provider can assign unique alias strings for its interfaces. If the name should remain associated with the same interface, the provider can make the strings persistent after the computer restarts and reinitializations.

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is an alias string that is returned in an NDIS_IF_COUNTED_STRING structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_STATISTICS

OID_GEN_BROADCAST_FRAMES_RCV

Article • 02/18/2023

As a query, the OID_GEN_BROADCAST_FRAMES_RCV OID specifies the number of broadcast packets that are received without errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

The count from this OID, combined with the count from OID_GEN_MULTICAST_FRAMES_RCV, is identical to the *ifInNUcastPkts* counter described in RFC 2863.

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_STATISTICS

OID_GEN_BYTES_RCV

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_BYTES_RCV OID to determine the total number of bytes that a miniport adapter received.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

NDIS handles this OID for miniport drivers. See the OID_GEN_STATISTICS OID for more information about statistics.

The total byte count is the sum of the receive-directed byte count, receive-multicast byte count and receive-broadcast byte count. This value is the same as the sum of the values that are returned by the OID_GEN_DIRECTED_BYTES_RCV, OID_GEN_MULTICAST_BYTES_RCV, and OID_GEN_BROADCAST_BYTES_RCV OIDs.

The count is identical to the *ifInOctets* counter described in RFC 2863.

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_GET_NETCARD_TIME

Article • 02/18/2023

> ⓘ **Note**
>
> OID_GEN_CO_GET_NETCARD_TIME is the same as OID_GEN_GET_NETCARD_TIME.

The OID_GEN_CO_GET_NETCARD_TIME OID requests the miniport driver to return a NIC's local time, as derived from a clock on the NIC or from the network. The time is formatted as a GEN_GET_NETCARD_TIME structure, defined as follows:

```c++
typedef struct _GEN_GET_NETCARD_TIME{
    ULONGLONG   ReadTime;
} GEN_GET_NETCARD_TIME, *PGEN_GET_NETCARD_TIME;
```

The member of this structure contains the following information:

ReadTime
The NIC's local time.

Remarks

The miniport driver specified the units for its local time in the **ClockPrecision** element of the GEN_GET_TIME_CAPS structure that the miniport driver returned in response to a previous OID_GEN_CO_GET_TIME_CAPS query.

If the miniport driver set the READABLE_LOCAL_CLOCK flag in its response to an OID_GEN_CO_GET_TIME_CAPS query, the NIC derives its local time from an onboard clock. If the miniport driver set the CLOCK_NETWORK_DERIVED flag in its response to an OID_GEN_CO_GET_TIME_CAPS query, the NIC derives its local time from the network.

If the local time is derived from an onboard clock, the miniport driver should be able to report the clock precision in parts per million. In general, a network-derived clock is preferable, because it is likely to be more precise and can be used to synchronize many machines attached to the same network or switch.

The miniport driver must return its local time synchronously in its response to the OID_GEN_CO_GET_NETCARD_TIME query since this query synchronizes protocol drivers with the NIC's local time. Protocol drivers should send the

OID_GEN_CO_GET_NETCARD_TIME query several times in succession to filter out response-time latencies.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_GET_TIME_CAPS

Article • 02/18/2023

> ⓘ **Note**
>
> OID_GEN_CO_GET_TIME_CAPS is the same as OID_GEN_GET_TIME_CAPS.

The OID_GEN_CO_GET_TIME_CAPS OID requests a miniport driver to return its capabilities for reporting a NIC's local time formatted as a GEN_GET_TIME_CAPS structure, which is defined as follows:

C++

```cpp
typedef struct _GEN_GET_TIME_CAPS{
    ULONG   Flags;
    ULONG   ClockPrecision;
} GEN_GET_TIME_CAPS, *PGEN_GET_TIME_CAPS;
```

The members of this structure contain the following information:

Flags
The following flags can be ORed together. All unspecified flags must be set to zero.

READABLE_LOCAL_CLOCK
When set, indicates the presence of a readable clock on the NIC. Even without such a hardware clock, a miniport driver can use the system clock by calling NdisGetCurrentSystemTime, so long as it reports the correct precision in the ClockPrecision member.

CLOCK_NETWORK_DERIVED
When set, indicates that the NIC's local time is derived from the network connection, as opposed to a free-running, onboard clock.

CLOCK_PRECISION
When set, indicates that the ClockPrecision member contains valid information.

RECEIVE_TIME_INDICATION_CAPABLE
When set, indicates that the NIC hardware can note the local time at which it receives the first cell of a received PDU and that the miniport driver propagates this receive time for each PDU when indicating the packet to a protocol.

TIMED_SEND_CAPABLE
When set, indicates that the NIC can schedule a packet for transmission according to its local time. Protocols can use NDIS_SET_PACKET_TIME_TO_SEND to set the TimeToSend timestamp in the out-of-band data block of a packet descriptor. Setting the timestamp does not affect when the packet is actually transmitted; instead, the timestamp is used for recordkeeping. A protocol driver can use the timestamp to determine how long it takes to complete the sending of a paket.

TIME_STAMP_CAPABLE
When set, indicates that the NIC can stamp (in the appropriate field of the outgoing packet) the time at which the first byte of the packet is transmitted and that the NIC can retrieve this time from the same field of an inbound packet.

ClockPrecision
Specifies the clock precision in parts per million. For this information to be considered valid, the CLOCK_PRECISION flag must be set.

Remarks

A miniport driver can provide support for certain timing parameters even in the absence of a local or network clock. In particular, a miniport driver can use the system clock for receive time indications, timed sends, and even time stamping. A NIC-based clock is better since it is likely to provide higher precision and to be accessible with lower latencies than the system clock. In all cases, the miniport driver must specify the precision of the clock that it uses. This allows protocols to determine how to best use the miniport driver's timing support.

If the miniport driver reports the presence of a readable clock, it must be prepared to immediately respond to an OID_GEN_GET_NETCARD_TIME query. The miniport driver's response to this call is time-critical and therefore must be synchronous.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_HARDWARE_STATUS

Article • 02/18/2023

The OID_GEN_CO_HARDWARE_STATUS OID specifies the current hardware status of the underlying NIC, as one of the following NDIS_HARDWARE_STATUS-type values:

NdisHardwareStatusReady
Available and capable of sending and receiving data over the wire.

NdisHardwareStatusInitializing
Initializing.

NdisHardwareStatusReset
Resetting.

NdisHardwareStatusClosing
Closing.

NdisHardwareStatusNotReady
Not ready.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_LINK_SPEED

Article • 02/18/2023

The OID_GEN_CO_LINK_SPEED OID requests the miniport driver to return its current transmit and receive speeds formatted as an NDIS_CO_LINK_SPEED structure, which is defined as follows:

```c++
typedef struct _NDIS_CO_LINK_SPEED{
    ULONG   Outbound;
    ULONG   Inbound;
} NDIS_CO_LINK_SPEED, *PNDIS_CO_LINK_SPEED;
```

The members of this structure contain the following information:

Outbound
The current transmit speed of the NIC. The unit of measurement is 100bps, so a value of 100,000 represents a hardware bit rate of 10 Mbps.

Inbound
The current receive speed of the NIC. The unit of measurement is 100bps, so a value of 100,000 represents a hardware bit rate of 10 Mbps.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_MAC_OPTIONS

Article • 02/18/2023

The OID_GEN_CO_MAC_OPTIONS OID is reserved. Do not use it in your code.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_MEDIA_CONNECT_STATUS

Article • 02/18/2023

The OID_GEN_CO_MEDIA_CONNECT_STATUS OID requests the miniport driver to return the connection status of the NIC on the network as one of the following system-defined values:

NdisMediaStateConnected

NdisMediaStateDisconnected

When a miniport driver senses that the network connection has been lost, it should call NdisMCoIndicateStatus with NDIS_STATUS_MEDIA_DISCONNECT. When the connection is restored, it should call NdisMCoIndicateStatus with NDIS_STATUS_MEDIA_CONNECT.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_MEDIA_IN_USE

Article • 02/18/2023

A complete list of the media types the NIC is currently supporting, defined as some, none (also called the NULL filter), or all of the following:

NdisMedium802_3
Ethernet (802.3).

NdisMedium802_5
Token Ring (802.5).

NdisMediumFddi
FDDI.

NdisMediumWan
WAN.

NdisMediumLocalTalk
LocalTalk.

NdisMediumDix
DIX.

NdisMediumArcnetRaw
ARCNET (raw).

NdisMediumArcnet878_2
ARCNET (878.2).

NdisMediumWirelessWan
Various types of NdisWirelessXxx media.

NdisMediumAtm
ATM.

If the underlying miniport driver returns **NULL** for this query or if an experimental media type is used, the driver must indicate receives with NdisMCoIndicateReceivePacket.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_MEDIA_SUPPORTED

Article • 02/18/2023

A complete list of the media types the NIC supports, as a proper subset of the following system-defined values:

NdisMedium802_3
Ethernet (802.3).

NdisMedium802_5
Token Ring (802.5).

NdisMediumFddi
FDDI.

NdisMediumWan
WAN.

NdisMediumLocalTalk
LocalTalk.

NdisMediumDix
DEC/Intel/Xerox (DIX) Ethernet.

NdisMediumArcnetRaw
ARCNET (raw).

NdisMediumArcnet878_2
ARCNET (878.2).

NdisMediumWirelessWan
Various types of NdisWirelessXxx media.

NdisMediumAtm
ATM.

NdisMediumIrda
Reserved for future use on Windows 2000 and later platforms.

Remarks

A LAN-emulation driver for ATM networks declares its medium as **NdisMedium802_3** , rather than **NdisMediumAtm**. Such a driver emulates Ethernet to higher-level NDIS drivers, complies with the ATM Forum's LANE, and provides UNI signaling support.

A wireless-WAN NIC driver must report its medium type as **NdisMediumWirelessWan**. However, such a miniport driver also must provide **NdisWWDIXEthernetFrames** header format to any bound protocol that selects this format, and the miniport driver can provide its NIC's native header format as well. To support existing LAN-based protocols, the driver writer can provide an NDIS intermediate driver to "translate" a wireless NIC's native header formats and medium-specific information into a form understood by existing protocols.

If the underlying miniport driver returns **NULL** for this query or if an experimental media type is used, the driver must indicate receives with NdisMCoIndicateReceivePacket.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_MINIMUM_LINK_SPEED

Article • 02/18/2023

The OID_GEN_CO_MINIMUM_LINK_SPEED OID requests the miniport driver to return its minimum transmit and receive speeds formatted as an NDIS_CO_LINK_SPEED structure, which is defined as follows:

```c++
typedef struct _NDIS_CO_LINK_SPEED{
    ULONG   Outbound;
    ULONG   Inbound;
} NDIS_CO_LINK_SPEED, *PNDIS_CO_LINK_SPEED;
```

The members of this structure contain the following information:

Outbound
The minimum transmit speed of the NIC. The unit of measurement is 100bps, so a value of 100,000 represents a hardware bit rate of 10 Mbps.

Inbound
The minimum receive speed of the NIC. The unit of measurement is 100bps, so a value of 100,000 represents a hardware bit rate of 10 Mbps.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_NETCARD_LOAD

Article • 02/18/2023

ⓘ Note

OID_GEN_CO_NETCARD_LOAD is the same as OID_GEN_NETCARD_LOAD.

The OID_GEN_CO_NETCARD_LOAD OID returns the relative load on the transmit system of a connection-oriented miniport driver. The miniport driver derives this number by calculating the difference between the amount of data delivered for transmission from protocols and the amount of data actually sent, as indicated by the packets returned to protocols with NdisMCoSendComplete. The result is the amount of outstanding transmit data in the miniport driver at any time.

Because this statistic changes at a very high frequency, the miniport driver port should filter it. The simplest filtering method is to maintain a running average of samples of the outstanding transmit data. For example, each time MiniportCoSendPackets is called, the miniport driver could add the submitted packet size to a miniport driver-defined variable called *OutstandingBytes*. Each time the miniport driver calls NdisMCoSendComplete, the miniport driver would then subtract the returned packet size from *OutstandingBytes*. The miniport driver must also maintain a running average, which is the value that the miniport driver should return in response to the OID_GEN_CO_NETCARD_LOAD query. This variable, which could be called *RunningAverage*, must be updated on each *MiniportCoSendPackets*, as follows:

```C++
RunningAverage = [(RunningAverage * C) + (OutstandingBytes * (128 - C))] /
128;
```

In this case, 1 < *C* < 128. Larger values of *C* produce smoother filtering.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_PROTOCOL_OPTIONS

Article • 02/18/2023

A bitmask that defines optional properties of the protocol driver. A protocol informs NDIS of its properties, which can optionally take advantage of them. If the protocol driver does not set its flags on a binding, NDIS assumes they are all clear.

The following flags are currently defined:

NDIS_PROT_OPTION_ESTIMATED_LENGTH
Indicates that packets can be indicated at the worst-case estimate of packet size, instead of an exact value, to this protocol.

NDIS_PROT_OPTION_NO_LOOPBACK
The protocol does not require loopback support on the binding.

NDIS_PROT_OPTION_NO_RSVD_ON_RCVPKT
The protocol does not use the **ProtocolReserved** section of indicated receive packets. This allows NDIS to indicate a receive packet to more than one protocol.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_RCV_CRC_ERROR

Article • 02/18/2023

The OID_GEN_CO_RCV_CRC_ERROR OID specifies the number of PDUs received with cyclic redundancy check (CRC) errors.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_RCV_PDUS_ERROR

Article • 02/18/2023

The OID_GEN_CO_RCV_PDUS_ERROR OID specifies the number of PDUs that a NIC received but did not indicate to bound protocols due to errors.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_RCV_PDUS_NO_BUFFER

Article • 02/18/2023

The OID_GEN_CO_RCV_PDUS_NO_BUFFER OID specifies the number of PDUs that the NIC could not receive because of a lack of NIC receive buffer space. Instead of providing the exact number, some NICs provide only the number of times that they have missed at least one PDU because of such a problem.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_RCV_PDUS_OK

Article • 02/18/2023

The OID_GEN_CO_RCV_PDUS_OK OID specifies the number of PDUs the NIC received without errors and indicated to bound protocols.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_SUPPORTED_GUIDS

Article • 02/18/2023

The OID_GEN_CO_SUPPORTED_GUIDS OID requests the miniport driver to return an array of structures of the type NDIS_GUID. Each structure in the array specifies the mapping of a custom GUID (globally unique identifier) to either a custom OID or to an NDIS_STATUS that the miniport driver sends through NdisMCoIndicateStatusEx.

The NDIS_GUID structure is defined as follows:

C++

```
typedef struct _NDIS_GUID {
    GUID    Guid;
    union {
        NDIS_OID    Oid;
        NDIS_STATUS Status;
    };
    ULONG   Size;
    ULONG   Flags;
} NDIS_GUID, *PNDIS_GUID;
```

The members of this structure contain the following information:

Guid
The custom GUID defined for the miniport driver.

Oid
The custom OID to which **Guid** maps.

Status
The NDIS_STATUS to which **Guid** maps.

Size
When the fNDIS_GUID_ARRAY flag is set, **Size** specifies the size in bytes of each data item in the array returned by the miniport driver. If the fNDIS_GUID_ANSI_STRING or fNDIS_GUID_NDIS_STRING flag is set, **Size** is set to -1. Otherwise, **Size** specifies the size in bytes of the data item that the GUID represents.

Flags
The following flags can be ORed together to indicate whether the GUID maps to an OID or to an NDIS_STATUS string and to indicate the type of data supplied for the GUID:

fNDIS_GUID_TO_OID
When set, indicates that the NDIS_GUID structure maps a GUID to an OID.

fNDIS_GUID_TO_STATUS
When set, indicates that the NDIS_GUID structure maps a GUID to an NDIS_STATUS string.

fNDIS_GUID_ANSI_STRING
When set, indicates that a null-terminated ANSI string is supplied for the GUID.

fNDIS_GUID_UNICODE_STRING
When set, indicates that a Unicode string is supplied for the GUID.

fNDIS_GUID_ARRAY
When set, indicates that an array of data items is supplied for the GUID. The specified Size indicates the length of each data item in the array.

fNDIS_GUID_ALLOW_READ
When set, indicates that all users are allowed to query this GUID.

fNDIS_GUID_ALLOW_WRITE
When set, indicates that all users are allowed to set this GUID.

Remarks

> **Note**
>
> By default, custom WMI GUIDs supplied by a miniport driver are only accessible to users with administrator privileges. A user with administrator privileges can always read or write to a custom GUID if the miniport driver supports the read or write operation for that GUID. Set the fNDIS_GUID_ALLOW_READ and fNDIS_GUID_ALLOW_WRITE flags to allow all users to access a custom GUID.

Note that all custom GUIDs registered by a miniport driver must set either fNDIS_GUID_TO_OID or fNDIS_GUID_TO_STATUS (never set both). All other flags may be combined by using the OR operator as applicable.

In the following example, an NDIS_GUID structure maps a GUID to OID_GEN_CO_RCV_PDUS_NO_BUFFER:

C++

```
NDIS_GUID NdisGuid =  {{0x0a214809, 0xe35f, 0x11d0, 0x96, 0x92, 0x00,
 0xc0, 0x4f, 0xc3, 0x35, 0x8c},
 GUID_NDIS_GEN_CO_RCV_PDUS_NO_BUFFER,
 OID_GEN_CO_RCV_PDUS_NO_BUFFER,
 4,
 fNDIS_GUID_TO_OID};
```

A GUID is an identifier used by Windows Management Instrumentation (WMI) to obtain or set information. NDIS intercepts a GUID sent by WMI to an NDIS driver, maps the GUID to an OID, and sends the OID to the driver. The driver returns the data item(s) to NDIS, which then returns the data to WMI.

NDIS also translates changes in NIC status into GUIDs recognized by WMI. When a miniport driver reports a change in NIC status with NdisMCoIndicateStatusEx, NDIS translates the NDIS_STATUS indicated by the miniport driver into a GUID that NDIS sends to WMI.

If a connection-oriented miniport driver supports customs GUIDs, it must support OID_GEN_CO_SUPPORTED_GUIDS, which returns to NDIS the mapping of custom GUIDs to custom OIDs or NDIS_STATUS strings. After querying the miniport driver with OID_GEN_CO_SUPPORTED_GUIDS, NDIS registers the miniport driver's custom GUIDs with WMI.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_SUPPORTED_LIST

Article • 02/18/2023

The OID_GEN_CO_SUPPORTED_LIST OID specifies an array of OIDs for objects that the underlying driver or its NIC supports. Objects include general, media-specific, and implementation-specific objects.

The underlying driver should order the OID list it returns in increasing numeric order. NDIS forwards a subset of the returned list to protocols that make this query. That is, NDIS filters any supported statistics OIDs out of the list since protocols never make statistics queries subsequently.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_TRANSMIT_QUEUE_LENGTH

Article • 02/18/2023

The OID_GEN_CO_TRANSMIT_QUEUE_LENGTH OID specifies the number of PDUs currently queued for transmission, whether on the NIC or in a driver-internal queue. The number returned is always the total number of PDUs currently queued, which can include unsubmitted send requests queued in the NDIS library.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_VENDOR_DESCRIPTION

Article • 02/18/2023

A pointer to a null-terminated, counted string describing the NIC.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_VENDOR_DRIVER_VERSION

Article • 02/18/2023

The vendor-assigned version number of the NIC driver.

This OID is two bytes in length; the low-order half of the return value specifies the minor version, while the high-order half specifies the major version.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_VENDOR_ID

Article • 02/18/2023

A 3-byte IEEE-registered vendor code, followed by a single byte that the vendor assigns to identify a particular NIC.

The IEEE code uniquely identifies the vendor and is the same as the three bytes appearing at the beginning of the NIC hardware address.

Vendors without an IEEE-registered code should use the value 0xFFFFFF.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_XMIT_PDUS_ERROR

Article • 02/18/2023

The OID_GEN_CO_XMIT_PDUS_ERROR OID specifies the number of PDUs a NIC failed to transmit.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CO_XMIT_PDUS_OK

Article • 02/18/2023

The OID_GEN_CO_XMIT_PDUS_OK OID specifies the number of PDUs transmitted without errors.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_CURRENT_LOOKAHEAD

Article • 02/18/2023

As a query, the OID_GEN_CURRENT_LOOKAHEAD OID returns the number of bytes of received packet data that will be indicated to the protocol driver. This specification does not include the header.

As a set, the OID_GEN_CURRENT_LOOKAHEAD OID specifies the number of bytes of received packet data that the miniport driver should indicate to the protocol driver. This specification does not include the header.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory. (see Remarks section)

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS handles query and unsuccessful set requests for NDIS 6.0 and later miniport drivers. NDIS obtains the information from the miniport driver during initialization and miniport adapter restart. However, NDIS sends valid set requests to the miniport driver.

For a query, NDIS returns the largest lookahead size from among all the bindings. A protocol driver can set a suggested value for the number of bytes to be used in its binding; however, the underlying miniport driver is never required to limit its indications to the value set.

If the underlying driver supports multipacket receive indications, bound protocol drivers are given full net packets on every indication. Consequently, this value is identical to that returned for OID_GEN_RECEIVE_BLOCK_SIZE.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_RECEIVE_BLOCK_SIZE

OID_GEN_CURRENT_PACKET_FILTER

Article • 02/18/2023

As a query, the OID_GEN_CURRENT_PACKET_FILTER OID reports the types of net packets that are in receive indications from a miniport driver.

As a set, the OID_GEN_CURRENT_PACKET_FILTER OID specifies the types of net packets for which a protocol receives indications from a miniport driver.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory. (see Remarks section)

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

For NDIS 6.0 and later miniport drivers, the query is not requested and the set is mandatory. NDIS handles the query for miniport drivers. The miniport driver reports the packet filter information during initialization.

The miniport driver reports its medium type as one for which the system provides a filter library. The packet filter uses the OR operation to inclusively combine the following types:

NDIS_PACKET_TYPE_DIRECTED
Directed packets. Directed packets contain a destination address equal to the station address of the NIC.

NDIS_PACKET_TYPE_MULTICAST
Multicast address packets sent to addresses in the multicast address list.

A protocol driver can receive Ethernet (802.3) multicast packets by specifying the multicast or functional address packet type. Setting the multicast address list or functional address determines which multicast address groups the NIC driver enables.

NDIS_PACKET_TYPE_ALL_MULTICAST
All multicast address packets, not just the ones enumerated in the multicast address list.

NDIS_PACKET_TYPE_BROADCAST
Broadcast packets.

NDIS_PACKET_TYPE_PROMISCUOUS
Specifies all packets regardless of whether VLAN filtering is enabled or not and whether the VLAN identifier matches or not.

NDIS_PACKET_TYPE_ALL_FUNCTIONAL
All functional address packets, not just the ones in the current functional address.

NDIS_PACKET_TYPE_ALL_LOCAL
All packets sent by installed protocols and all packets indicated by the NIC that is identified by a given *NdisBindingHandle* .

NDIS_PACKET_TYPE_FUNCTIONAL
Functional address packets sent to addresses included in the current functional address.

NDIS_PACKET_TYPE_GROUP
Packets sent to the current group address.

NDIS_PACKET_TYPE_MAC_FRAME
NIC driver frames that a Token Ring NIC receives.

NDIS_PACKET_TYPE_SMT
SMT packets that an FDDI NIC receives.

NDIS_PACKET_TYPE_SOURCE_ROUTING
All source routing packets. If the protocol driver sets this bit, the NDIS library attempts to act as a source routing bridge.

For miniport adapters whose media type is **NdisMedium802_3** or **NdisMedium802_5**, NDIS disables packet reception, along with multicast and functional addresses during a call to the NdisOpenAdapterEx function.

For miniport adapters with all other media types, the protocol driver can begin receiving packets at any time during the NdisOpenAdapterEx call. Note that the protocol can even receive packets before **NdisOpenAdapterEx** returns. In general, packet filtering is best effort, and protocol drivers must be prepared to handle receive indications even when the packet filter is zero.

For a query, NDIS returns the binding filters that are combined using the OR operator.

For a set, the specified packet filter replaces the previous packet filter for the binding. If the miniport driver previously enabled a packet type but the protocol driver does not specify that type in a new filter, the protocol driver will not receive packets of this type.

For miniport adapters whose media type is **NdisMedium802_3** or **NdisMedium802_5**, if the miniport driver does not set a bit for a particular packet type in response to this query, the protocol driver will not receive packets of that type. Consequently, a protocol driver can disable packet reception by calling the **NdisOidRequest** or **NdisCoOidRequest** function using a filter of zero.

For miniport adapters with all other media types, NDIS does not check the packet type. For these media types, a protocol driver cannot disable packet reception by specifying a filter of zero.

When a miniport driver's *MiniportInitializeEx* function is called, the miniport driver's packet filter should be set to zero. When the packet filter is zero, receive indications are disabled. After a miniport driver's *MiniportInitializeEx* function has returned, a protocol driver can set OID_GEN_CURRENT_PACKET_FILTER to a nonzero value, thereby enabling the miniport driver to indicate received packets to that protocol.

If promiscuous mode is enabled with the NDIS_PACKET_TYPE_PROMISCUOUS bit, the protocol driver continues to receive packets even if the sending network node does not direct them to it. NDIS then sends the protocol driver all packets the NIC receives.

Setting a specific packet filter does not alter the packet filter for other protocol drivers that are bound to (or above) the same NIC. For example, if one bound protocol enables promiscuous mode, other bound protocol drivers do not receive packets that they have not specifically requested with their own packet filters.

Native 802.11 Packet Filters

The Native 802.11 miniport driver must only support the following standard packet filter types:

- NDIS_PACKET_TYPE_DIRECTED
- NDIS_PACKET_TYPE_MULTICAST
- NDIS_PACKET_TYPE_BROADCAST

- NDIS_PACKET_TYPE_PROMISCUOUS

When enabled, these standard packet filters are only applicable to 802.11 data packets.

In addition, the Native 802.11 miniport driver must support the following packet filter types, which are specific to the Native 802.11 media:

NDIS_PACKET_TYPE_802_11_RAW_DATA
An 802.11 media access control (MAC) protocol data unit (MPDU) frame, which contains all of the data in the format received by the 802.11 station. When this filter is set, the driver must indicate every unmodified MPDU fragment before it indicates the MAC service data unit (MSDU) packet reassembled from the MPDU fragments.

If an MPDU fragment is encrypted, it must not decrypt the fragment before it is indicated. However, the miniport driver must decrypt each MPDU fragment before reassembling and indicating the MSDU packet.

If enabled, this filter type only affects other standard packet filters, such as NDIS_PACKET_TYPE_DIRECTED or NDIS_PACKET_TYPE_BROADCAST.

For more information about the method for indicating raw 802.11 data packets, see Indicating Raw 802.11 Packets.

NDIS_PACKET_TYPE_802_11_DIRECTED_MGMT
Directed 802.11 management packets. Directed packets contain a destination address equal to the station address of the NIC.

NDIS_PACKET_TYPE_802_11_MULTICAST_MGMT
Multicast 802.11 management packets sent to addresses in the multicast address list.

NDIS_PACKET_TYPE_802_11_ALL_MULTICAST_MGMT
All multicast 802.11 management packets received by the 802.11 station, regardless of whether the destination address in the 802.11 MAC header is in the multicast address list.

NDIS_PACKET_TYPE_802_11_BROADCAST_MGMT
Broadcast 802.11 management packets received by the 802.11 station.

NDIS_PACKET_TYPE_802_11_PROMISCUOUS_MGMT
All 802.11 management packets received by the 802.11 station.

NDIS_PACKET_TYPE_802_11_RAW_MGMT
An 802.11 MPDU management frame, which contains all of the data in the format received by the 802.11 station. When this filter is set, the driver must indicate every

unmodified MPDU fragment before it indicates the MAC management protocol data unit (MMPDU) packet reassembled from the MPDU fragments.

If enabled, this filter type only affects other 802.11 management packet filters, such as NDIS_PACKET_TYPE_802_11_DIRECTED_MGMT or NDIS_PACKET_TYPE_802_11_MULTICAST_MGMT.

For more information about the method for indicating raw 802.11 management packets, see Indicating Raw 802.11 Packets.

NDIS_PACKET_TYPE_802_11_DIRECTED_CTRL
Directed 802.11 control packets. Directed packets contain a destination address equal to the station address of the NIC.

NDIS_PACKET_TYPE_802_11_BROADCAST_CTRL
Broadcast 802.11 control packets received by the 802.11 station.

NDIS_PACKET_TYPE_802_11_PROMISCUOUS_CTRL
All 802.11 control packets received by the 802.11 station.

If a miniport driver is operating in Native 802.11 Network Monitor (NetMon) or Extensible Access Point (AP) modes, the driver must enable the following packet filters through a set request of OID_GEN_CURRENT_PACKET_FILTER.

- NDIS_PACKET_TYPE_PROMISCUOUS
- NDIS_PACKET_TYPE_802_11_RAW_DATA
- NDIS_PACKET_TYPE_802_11_PROMISCUOUS_MGMT
- NDIS_PACKET_TYPE_802_11_RAW_MGMT
- NDIS_PACKET_TYPE_802_11_PROMISCUOUS_CTRL

A miniport driver operating in other Native 802.11 modes besides NetMon must not enable these packet filter settings, with the exception of NDIS_PACKET_TYPE_802_11_PROMISCUOUS_CTRL. A miniport driver that is not operating in NetMon mode can optionally enable NDIS_PACKET_TYPE_802_11_PROMISCUOUS_CTRL through a set request of OID_GEN_CURRENT_PACKET_FILTER.

Note When the miniport driver is in Native 802.11 modes other than NetMon, and OID_GEN_CURRENT_PACKET_FILTER is set, the driver must not fail the set request if any promiscuous or raw filter settings are enabled in the OID data.

For more information about the NetMon and ExtAP operating modes, see the following topics:

Network Monitor Operation Mode

Extensible Access Point Operation Mode

OID_GEN_DEVICE_PROFILE

Article • 02/18/2023

The OID_GEN_DEVICE_PROFILE OID is obsolete. NDIS and NDIS drivers do not use this OID.

Requirements

Version	Not supported.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_DIRECTED_BYTES_RCV

Article • 02/18/2023

As a query, the OID_GEN_DIRECTED_BYTES_RCV OID specifies the number of bytes in directed packets that are received without errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

The count is identical to the *ifInUcastPkts* counter described in RFC 2863.

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_DIRECTED_BYTES_XMIT

Article • 02/18/2023

As a query, the OID_GEN_DIRECTED_BYTES_XMIT OID specifies the number of bytes in directed packets that are transmitted without errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

For general information about statistics OIDs, see General Statistics.

Requirements

See also

OID_GEN_STATISTICS

OID_GEN_DISCONTINUITY_TIME

Article • 02/18/2023

As a query, use the OID_GEN_DISCONTINUITY_TIME OID to determine the discontinuity time of a network interface (*ifCounterDiscontinuityTime* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

This OID returns the time, starting from the last computer restart, when the interface had a discontinuity in maintaining the statistics counters. For example, there was a discontinuity because the interface was disabled or the associated adapter was removed from the computer. For more information about the statistics counters, see OID_GEN_STATISTICS. To get the current time, an interface provider can call the **NdisGetSystemUpTimeEx** function.

If no such discontinuity occurred since the last re-initialization of the interface this value should be zero. If the interface provider does not track discontinuity time, this value should be zero.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is a ULONG64 value that specifies the discontinuity time, in milliseconds, since the last computer restart.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS Network Interface OIDs

OID_GEN_DRIVER_VERSION

Article • 02/18/2023

As a query, the OID_GEN_DRIVER_VERSION OID specifies the NDIS version in use by the miniport driver.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS handles this OID for NDIS 6.0 and later miniport drivers.

The high byte is the major version number; the low byte is the minor version number.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_ENUMERATE_PORTS

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_ENUMERATE_PORTS OID to determine the characteristics of the active NDIS ports that are associated with an underlying miniport adapter.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

NDIS handles this OID and miniport drivers do not receive this OID query.

If the query succeeds, NDIS returns NDIS_STATUS_SUCCESS and provides the results of the query in an NDIS_PORT_ARRAY structure. The **NumberOfPorts** member of NDIS_PORT_ARRAY contains the number of active ports that are associated with the miniport adapter. The **Ports** member of NDIS_PORT_ARRAY contains a list of pointers to NDIS_PORT_CHARACTERISTICS structures. Each NDIS_PORT_CHARACTERISTICS structure defines the characteristics of a single NDIDS port.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_PORT_ARRAY

NDIS_PORT_CHARACTERISTICS

OID_GEN_FRIENDLY_NAME

Article • 02/18/2023

As a query, the OID_GEN_FRIENDLY_NAME OID returns the friendly name of a miniport adapter.

Remarks

The OID_GEN_FRIENDLY_NAME OID returns the friendly name of a miniport adapter.

Friendly names are intended to help the user quickly and accurately identify a miniport adapter--for example, "PCI Ethernet Adapter" and "Virtual Private Networking Adapter" are considered friendly names.

Requirements

Version	Supported for NDIS 5.1 and later drivers in Windows Vista and later versions of Windows and later versions of Windows. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_HARDWARE_STATUS

Article • 02/18/2023

As a query, the OID_GEN_HARDWARE_STATUS OID specifies the current hardware status of the underlying NIC.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Obsolete.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The OID_GEN_HARDWARE_STATUS OID specifies the current hardware status of the underlying NIC as one of the following NDIS_HARDWARE_STATUS-type values:

NdisHardwareStatusReady
Available and capable of sending and receiving data over the wire

NdisHardwareStatusInitializing
Initializing

NdisHardwareStatusReset
Resetting

NdisHardwareStatusClosing
Closing

NdisHardwareStatusNotReady
Not ready

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_HD_SPLIT_CURRENT_CONFIG

Article • 02/18/2023

As a query, overlying drivers or administrative utilities can use the OID_GEN_HD_SPLIT_CURRENT_CONFIG OID to determine the current header-data split configuration of a miniport adapter. A system administrator can use the GUID that is associated with this OID through the WMI interface.

Remarks

NDIS handles this OID on behalf of the miniport driver. NDIS maintains the current header-data split configuration information based on the miniport driver initialization attributes and the NDIS_STATUS_HD_SPLIT_CURRENT_CONFIG status indication.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_HD_SPLIT_CURRENT_CONFIG structure.

Requirements

Version	Supported in NDIS 6.1 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_HD_SPLIT_CURRENT_CONFIG

NDIS_OID_REQUEST

NDIS_STATUS_HD_SPLIT_CURRENT_CONFIG

OID_GEN_HD_SPLIT_PARAMETERS

Article • 02/18/2023

As a set, NDIS and overlying drivers or user-mode applications use the OID_GEN_HD_SPLIT_PARAMETERS OID to set the current header-data split settings of a miniport adapter. NDIS 6.1 and later miniport drivers that provide header-data split services must support this OID. Otherwise, this OID is optional.

Remarks

The **InformationBuffer** member of NDIS_OID_REQUEST structure contains an NDIS_HD_SPLIT_PARAMETERS structure.

NDIS might set the OID_GEN_HD_SPLIT_PARAMETERS OID when an NDIS 5.*x* protocol driver binds to an NDIS 6.1 miniport. NDIS processes this OID before passing it to the miniport driver and updates the miniport adapter's ***HeaderDataSplit** standardized keyword, if required. If header-data split is disabled, NDIS does not send this OID to the miniport adapter.

NDIS will send this OID to the miniport driver only if header-data split was enabled with the NDIS_HD_SPLIT_ENABLE_HEADER_DATA_SPLIT flag in the NDIS_HD_SPLIT_ATTRIBUTES structure during miniport initialization.

Requirements

Version	Supported in NDIS 6.1 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_HD_SPLIT_ATTRIBUTES

NDIS_HD_SPLIT_PARAMETERS

NDIS_OID_REQUEST

OID_GEN_INIT_TIME_MS

Article • 02/18/2023

As a query, the OID_GEN_INIT_TIME_MS OID returns the time in milliseconds that a driver required to initialize.

Remarks

The OID_GEN_INIT_TIME_MS OID returns the time in milliseconds that a driver required to initialize.

Requirements

Version	Supported for NDIS 5.1 and later drivers in Windows Vista and later versions of Windows and later versions of Windows. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_INTERFACE_INFO

Article • 02/18/2023

As a query, use the OID_GEN_INTERFACE_INFO OID to obtain the current state and statistics information for a network interface.

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the query succeeds, the interface provider returns NDIS_STATUS_SUCCESS, and the result of the query is an **NDIS_INTERFACE_INFORMATION** structure. This structure contains information that changes during the lifetime of the interface.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_INTERFACE_INFORMATION

NDIS Network Interface OIDs

OID_GEN_INTERRUPT_MODERATION

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_INTERRUPT_MODERATION OID to determine if interrupt moderation is enabled on a miniport adapter. If the query succeeds, NDIS returns an NDIS_INTERRUPT_MODERATION_PARAMETERS structure that contains the current interrupt moderation settings.

As a set, NDIS and overlying drivers use the OID_GEN_INTERRUPT_MODERATION OID to enable or disable the interrupt moderation on a miniport adapter.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory. Set and query.

Remarks

For a query, if a miniport driver does not support interrupt moderation, the driver must specify **NdisInterruptModerationNotSupported** in the **InterruptModeration** member of the NDIS_INTERRUPT_MODERATION_PARAMETERS structure.

For a set, if the driver reported **NdisInterruptModerationNotSupported** in response to the OID_GEN_INTERRUPT_MODERATION query, the driver should return NDIS_STATUS_INVALID_DATA in response to the set request. The miniport driver receives an NDIS_INTERRUPT_MODERATION_PARAMETERS structure. If the **InterruptModeration** member of NDIS_INTERRUPT_MODERATION_PARAMETERS is set to **NdisInterruptModerationEnabled**, the miniport driver should enable interrupt moderation. Otherwise, it should disable interrupt moderation.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_INTERRUPT_MODERATION_PARAMETERS

OID_GEN_ISOLATION_PARAMETERS

Article • 02/18/2023

NDIS and overlying drivers issue an object identifier (OID) request of OID_GEN_ISOLATION_PARAMETERS to obtain the multi-tenancy configuration (isolation) parameters that are set on a VM network adapter's port.

Although each routing domain is configured separately on the port, this OID returns parameters for all of the routing domains in a single query.

An overlying driver should issue this OID in two steps:

1. Io query the required buffer size, issue the OID query with the **Size** member of the **Header** member of the NDIS_ISOLATION_PARAMETERS structure set to **NDIS_SIZEOF_NDIS_ISOLATION_PARAMETERS_REVISION_1**. (See **NDIS_STATUS_INVALID_LENGTH** below.)
2. Issue the OID with an **InformationBuffer** of the required size.

If the OID query request is completed successfully, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data, in order:

1. An NDIS_ISOLATION_PARAMETERS structure

2. One or more NDIS_ROUTING_DOMAIN_ENTRY structures, one for each routing domain

3. One or more NDIS_ROUTING_DOMAIN_ISOLATION_ENTRY structures, grouped by routing domain

In each NDIS_ROUTING_DOMAIN_ENTRY structure, the **FirstIsolationInfoEntryOffset** member contains the offset from the beginning of the OID information buffer (that is, the beginning of the buffer that the **InformationBuffer** member of the NDIS_OID_REQUEST structure points to) to the first NDIS_ROUTING_DOMAIN_ISOLATION_ENTRY for that routing domain. The offset in the **NextIsolationInfoEntryOffset** member of the last structure in the list is zero.

If no multi-tenancy configuration parameters are set on the VM network adapter, the network adapter miniport driver sets the **DATA.QUERY_INFORMATION.BytesWritten** member of the NDIS_OID_REQUEST structure to zero and returns **NDIS_STATUS_SUCCESS**. In this case, the data within the **DATA.QUERY_INFORMATION.InformationBuffer** member is not modified by the miniport driver.

Remarks

Return Status Codes

The VM network adapter miniport driver returns one of the following status codes for this OID request:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the requested information. The VM network adapter miniport driver sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size, in bytes, that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.40 and later.
Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_LAST_CHANGE

Article • 02/18/2023

As a query, use the OID_GEN_LAST_CHANGE OID to determine the time of the last operational state change of a network interface (*ifLastChange* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

This OID returns the time, starting from the last computer restart, when the interface entered its current operational state. For more information about the operational state, see **NDIS_STATUS_OPER_STATUS** and OID_GEN_OPERATIONAL_STATUS. To get the current time, an interface provider can call the **NdisGetSystemUpTimeEx** function.

If the current operational state was entered before the last reinitialization of the interface, this value should be zero. . If the interface provider does not track operational state change time, the value should be zero.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is a ULONG64 value that specifies the state change time, in milliseconds, since the last computer restart.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_OPERATIONAL_STATUS

NDIS_STATUS_OPER_STATUS

NdisGetSystemUpTimeEx

NDIS Network Interface OIDs

OID_GEN_LINK_PARAMETERS

Article • 02/18/2023

As a set, NDIS and overlying drivers use the OID_GEN_LINK_PARAMETERS OID to set the current link state of a miniport adapter. The miniport driver receives the duplex state, link speeds, and pause functions in an NDIS_LINK_PARAMETERS structure.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

The NDIS_LINK_PARAMETERS structure is defined as follows:

ManagedCPlusPlus

```
    typedef struct _NDIS_LINK_PARAMETERS {
         NDIS_OBJECT_HEADER Header;
         NDIS_MEDIA_DUPLEX_STATE MediaDuplexState;
         ULONG64 XmitLinkSpeed;
         ULONG64 RcvLinkSpeed;
         NDIS_SUPPORTED_PAUSE_FUNCTIONS PauseFunctions;
         ULONG AutoNegotiationFlags;
    } NDIS_LINK_PARAMETERS, *PNDIS_LINK_PARAMETERS;
```

This structure contains the following members:

Header
The **NDIS_OBJECT_HEADER** structure for the NDIS_LINK_PARAMETERS structure. Set the **Type** member of the structure that **Header** specifies to NDIS_OBJECT_TYPE_DEFAULT, the **Revision** member to NDIS_LINK_PARAMETERS_REVISION_1, and the **Size** member to NDIS_SIZEOF_LINK_PARAMETERS_REVISION_1.

MediaDuplexState
The media duplex state. This value is the same as the value that is returned by the OID_GEN_MEDIA_DUPLEX_STATE OID.

XmitLinkSpeed
The transmit link speed in bits per second.

RcvLinkSpeed
The receive link speed in bits per second.

PauseFunctions
The type of support for the IEEE 802.3 pause frames. This member must be one of the following pause functions:

NdisPauseFunctionsUnsupported
The adapter or link partner does not support pause frames.

NdisPauseFunctionsSendOnly
The adapter and link partner support only sending pause frames from the adapter to the link partner.

NdisPauseFunctionsReceiveOnly
The adapter and link partner support only sending pause frames from the link partner to the adapter

NdisPauseFunctionsSendAndReceive
The adapter and link partner support sending and receiving pause frames in both transmit and receive directions.

AutoNegotiationFlags
The auto-negotiation settings for the miniport adapter. This member is created from a bitwise OR of the following flags:

NDIS_LINK_STATE_XMIT_LINK_SPEED_AUTO_NEGOTIATED
The adapter should auto-negotiate the transmit link speed with the link partner. If this flag is not set, the miniport driver should set the transmit link speed to the value that is specified in the **XmitLinkSpeed** member.

NDIS_LINK_STATE_RCV_LINK_SPEED_AUTO_NEGOTIATED
The adapter should auto-negotiate the receive link speed with the link partner. If this flag is not set, the miniport driver should set the receive link speed to the value that is specified in the **RcvLinkSpeed** member.

NDIS_LINK_STATE_DUPLEX_AUTO_NEGOTIATED
The adapter should auto-negotiate the duplex state with the link partner. If this flag is not set, the miniport driver should set the duplex state to the value that is specified in the **MediaDuplexState** member.

NDIS_LINK_STATE_PAUSE_FUNCTIONS_AUTO_NEGOTIATED
The miniport driver should auto-negotiate the support for pause frames with the other end. If this flag is not set, the miniport driver should use the pause frame support that is specified in the **PauseFunctions** member.

Remarks

Note Setting OID_GEN_LINK_PARAMETERS can cause a loss of connectivity. Miniport drivers must reconfigure the miniport adapter when this OID is set. For example, the miniport driver can reset the miniport adapter with the resulting loss of existing connections. The specific mechanism for reconfiguration is application dependent.

If the link state of the miniport adapter changes because of the OID_GEN_LINK_PARAMETERS set request, the miniport driver should generate an NDIS_STATUS_LINK_STATE status indication to notify NDIS and overlying drivers of the new link state.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_OBJECT_HEADER

NDIS_STATUS_LINK_STATE

OID_GEN_MEDIA_DUPLEX_STATE

OID_GEN_LINK_SPEED

Article • 02/18/2023

As a query, the OID_GEN_LINK_SPEED OID specifies the maximum speed of the NIC.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later miniport drivers
Obsolete. (see Remarks section)

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The OID_GEN_LINK_STATE is the NDIS 6.0 and later and later equivalent of this OID. However NDIS 6.0 and later miniport drivers must use the **NDIS_STATUS_LINK_STATE** status indication instead to indicate link speed changes.

The unit of measurement is 100 bps, so a value of 100,000 represents a hardware bit rate of 10 Mbps.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_LINK_STATE

OID_GEN_LINK_STATE

OID_GEN_LINK_SPEED_EX

Article • 02/18/2023

As a query, the OID_GEN_LINK_SPEED_EX OID provides the transmit and receive link speeds of an interface.

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

NDIS uses this OID to query the link speed of an NDIS network interface provider. Only NDIS interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

This OID returns the link speeds in an **NDIS_LINK_SPEED** structure.

Miniport drivers supply the link speed during initialization and provide updated link speeds with status indications.

To specify the link speeds in a miniport driver, set the **XmitLinkSpeed** and **RcvLinkSpeed** members of the **NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES** structure that the miniport driver passes to the **NdisMSetMiniportAttributes** function.

Requirements

Header	Ntddndis.h (include Ndis.h)

NDIS Network Interface OIDs

OID_GEN_LINK_STATE

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_LINK_STATE OID to determine the current link state of a miniport adapter. The miniport driver receives the link state in an NDIS_LINK_STATE structure.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

Miniport drivers supply the link state during initialization and provide updates with status indications.

To specify the link state, set the **MediaConnectState**, **MediaDuplexState**, **XmitLinkSpeed**, **RcvLinkSpeed**, **PauseFunctions**, and **AutoNegotiationFlags** members of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure that the miniport driver passes to the **NdisMSetMiniportAttributes** function.

If a miniport driver does not support this OID, the driver should return NDIS_STATUS_NOT_SUPPORTED. If the miniport driver supports this OID, it returns the connection state, duplex state, and link speeds in an NDIS_LINK_STATE structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_MEDIA_CONNECT_STATUS_EX

OID_GEN_MEDIA_DUPLEX_STATE

OID_GEN_MAC_OPTIONS

Article • 02/18/2023

As a query, the OID_GEN_MAC_OPTIONS OID specifies a bitmask that defines optional properties of the underlying driver or a NIC.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS handles this OID for NDIS 6.0 and later miniport drivers.

A protocol that initiates this query can determine which of the flags the underlying driver sets, and can optionally take advantage of them.

The following flags are currently defined:

NDIS_MAC_OPTION_COPY_LOOKAHEAD_DATA
The protocol driver is free to access indicated data by any means. Some fast-copy functions have trouble accessing on-board device memory. Miniport drivers that indicate data out of mapped device memory should never set this flag. If a miniport driver does set this flag, it relaxes the restriction on fast-copy functions.

NDIS_MAC_OPTION_RECEIVE_SERIALIZED
The miniport driver indicates packets in a serial manner. That is, such a driver does not enter a new receive indication until the previous receive, if any, has been completed.

NDIS_MAC_OPTION_TRANSFERS_NOT_PEND
The miniport driver never completes receive indications asynchronously.

A miniport driver that indicates receive operations with the **NdisMIndicateReceiveNetBufferLists** function should set this flag.

NDIS_MAC_OPTION_NO_LOOPBACK
The NIC has no internal loopback support so NDIS will manage loopbacks on behalf of this driver. A miniport driver cannot provide its own software loopback as efficiently as NDIS, so every miniport driver should set this flag unless a NIC has hardware loopback support. WAN miniport drivers must set this flag.

NDIS_MAC_OPTION_FULL_DUPLEX
The miniport driver supports full-duplex transmits and indications on SMP platforms.

Note This flag has been deprecated for use by NDIS 5.0 and later miniport drivers. NDIS 5.0 and later ignores this flag.

NDIS_MAC_OPTION_EOTX_INDICATION
This flag is obsolete.

NDIS_MAC_OPTION_8021P_PRIORITY
The NIC and its driver support 802.1p packet priority. For more information, see Packet Priority. Packet-priority values are received in **NET_BUFFER** structures from higher-layer drivers. The appropriate information is generated in the MAC headers of packets and transmitted over the network. In addition, this NIC and its driver support extracting the appropriate information from the MAC headers of packets received from the network. This information is forwarded in NET_BUFFER structures to higher-layer drivers.

Note NDIS 6.0 and later and later and later miniport drivers must set the NDIS_MAC_OPTION_8021P_PRIORITY flag.

NDIS_MAC_OPTION_SUPPORTS_MAC_ADDRESS_OVERWRITE
NDIS sets this flag when a miniport driver calls the **NdisReadNetworkAddress** function.

NDIS_MAC_OPTION_RECEIVE_AT_DPC
This flag is obsolete.

NDIS_MAC_OPTION_8021Q_VLAN
The miniport driver can assign and remove VLAN identifier (ID) marking in the MAC headers of packets. The driver maintains a configured VLAN ID for each NIC that the driver handles. The driver filters out incoming packets that do not belong to the VLAN to which a NIC is associated and marks outgoing packets with the VLAN ID. During the driver's *MiniportInitializeEx* function for a particular NIC, the driver initially sets the NIC's

VLAN ID to zero. The driver's *MiniportInitializeEx* function then reads the following configuration parameter from the registry, and, if the parameter is present, sets the NIC's VLAN ID to the parameter's value.

syntax

```
VlanId, REG_DWORD
```

NDIS_MAC_OPTION_RESERVED
Reserved for NDIS internal use.

Note A miniport driver that sets the NDIS_MAC_OPTION_8021Q_VLAN flag must also set the NDIS_MAC_OPTION_8021P_PRIORITY flag. In other words, a miniport driver that supports 802.1Q must also support 802.1p.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

MiniportInitializeEx

NdisReadNetworkAddress

NET_BUFFER

OID_GEN_MACHINE_NAME

Article • 02/18/2023

As a set, the OID_GEN_MACHINE_NAME OID indicates the local computer name to a miniport driver.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

The information buffer passed in this request contains an array of Unicode characters that represents the local computer name. The **InformationBufferLength** value that is supplied to the *MiniportOidRequest* function specifies the length of this array in bytes, not including a NULL terminator.

NDIS sets OID_GEN_MACHINE_NAME only once after a miniport driver completes initialization. Under Windows XP, NDIS does not dynamically notify miniport drivers of a change in the computer name. After changing the computer name, a user must restart the computer so that NDIS notifies miniport drivers of the new computer name.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

MiniportOidRequest

OID_GEN_MAX_LINK_SPEED

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_MAX_LINK_SPEED OID to determine the maximum supported transmit and receive link speeds of a miniport adapter.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

The miniport driver supplies the maximum link speed during initialization.

To specify the maximum link speeds, set the **MaxXmitLinkSpeed** and **MaxRcvLinkSpeed** members of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure that the miniport driver passes to the NdisMSetMiniportAttributes function. If a miniport driver does not support this OID, the driver should return NDIS_STATUS_NOT_SUPPORTED. If the miniport driver supports this OID, it returns the maximum link speeds in an NDIS_LINK_SPEED structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_LINK_SPEED

NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES

NdisMSetMiniportAttributes

OID_GEN_MAXIMUM_FRAME_SIZE

Article • 02/18/2023

As a query, the OID_GEN_MAXIMUM_FRAME_SIZE OID specifies the maximum network packet size, in bytes, that the NIC supports. This specification does not include a header.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not Requested.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The miniport driver supplies the maximum frame size during initialization and during a restart. NDIS handles this OID query for NDIS 6.0 and later miniport drivers.

In response to this query from requesting transports, the miniport driver should indicate the maximum frame size that the transports can send, excluding the header. A miniport driver that emulates another medium type for binding to a transport must ensure that the maximum frame size for a protocol-supplied net packet does not exceed the size limitations for the true network medium. The same is true for a miniport driver that supports a NIC that requires inserting fields in frames. For example, to determine the maximum transfer unit (MTU), transports send this query to a NIC.

If the miniport driver supports 802.1p packet priority and 802.1Q virtual LAN (VLAN) tags, based on prior actions, if the miniport driver expects that frames must traverse old networks before priority values are removed, that miniport driver might indicate a smaller value in response to this query.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_MAXIMUM_LOOKAHEAD

Article • 02/18/2023

As a query, the OID_GEN_MAXIMUM_LOOKAHEAD OID specifies the maximum number of bytes that the NIC can provide as lookahead data. This specification does not include a header.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS 6.0 and later miniport drivers do not receive this OID request. NDIS handles this OID with a cached value that miniport drivers supply during initialization.

Upper-layer drivers examine lookahead data to determine whether a packet that is associated with the lookahead data is intended for one or more of their clients.

If the underlying driver supports multipacket receive indications, bound protocol drivers are given full net packets on every indication. Consequently, this value is identical to that returned for OID_GEN_RECEIVE_BLOCK_SIZE.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_RECEIVE_BLOCK_SIZE

OID_GEN_MAXIMUM_SEND_PACKETS

Article • 02/18/2023

As a query, the OID_GEN_MAXIMUM_SEND_PACKETS OID specifies the maximum number of send packet descriptors that a miniport driver's *MiniportSendPackets* function can accept.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later miniport drivers
Obsolete.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS ignores any value returned by a deserialized driver in response to a query of OID_GEN_MAXIMUM_SEND_PACKETS. NDIS does not adjust the size of the array of packet descriptors that it supplies to a deserialized miniport driver's *MiniportSendPackets* function.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

MiniportSendPackets

OID_GEN_MAXIMUM_TOTAL_SIZE

Article • 02/18/2023

As a query, the OID_GEN_MAXIMUM_TOTAL_SIZE OID specifies the maximum total packet length, in bytes, the NIC supports. This specification includes the header.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The returned length specifies the largest packet size for the underlying medium. Thus, the returned length depends on the particular medium. A protocol driver might use this returned length as a gauge to determine the maximum size packet that a miniport driver could forward to the protocol driver. If the protocol driver preallocates buffers, it allocates buffers accordingly. The returned length also specifies the largest packet that a protocol driver can pass to the **NdisSendNetBufferLists** function.

If the miniport driver for a NIC enables 802.1p packet priority(that is, the miniport driver specifies the NDIS_MAC_OPTION_8021P_PRIORITY bit in the OID_GEN_MAC_OPTIONS OID bitmask), then the miniport driver must specify its maximum total packet length as 4 bytes less than the maximum size of packets received or sent over the network. For example, if a NIC that has 802.1p packet priority enabled receives and sends packets on the wire that are 1514 bytes in length, the miniport driver for the NIC must report its maximum total packet length as 1510 bytes. The miniport driver must never indicate up to the bound protocol driver packets received over the network that are longer than the packet size specified by OID_GEN_MAXIMUM_TOTAL_SIZE. That is, even if the miniport driver receives packets over the network that are not marked with priority values but are still the maximum size that the underlying medium supports, the miniport driver can only indicate up packets that are no longer than the size specified by OID_GEN_MAXIMUM_TOTAL_SIZE.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NdisSendNetBufferLists

OID_GEN_MAC_OPTIONS

OID_GEN_MEDIA_CAPABILITIES

Article • 02/18/2023

The OID_GEN_MEDIA_CAPABILITIES OID is obsolete. NDIS and NDIS drivers do not use this OID.

Requirements

Version	Not supported.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_MEDIA_CONNECT_STATUS

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_CONNECT_STATUS OID requests the connection status of the NIC on the network.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS handles this OID for NDIS 6.0 and later miniport drivers.

The OID_GEN_MEDIA_CONNECT_STATUS OID requests the connection status of the NIC on the network as one of the following system-defined values:

NdisMediaStateConnected

NdisMediaStateDisconnected

When a miniport driver senses that the network connection has been lost, it must also call the NdisMIndicateStatusEx or NdisMCoIndicateStatusEx function with NDIS_STATUS_MEDIA_DISCONNECT (for NDIS 5.1) or NDIS_STATUS_LINK_STATE with **MediaConnectStateDisconnected** in the MediaConnectState property (for NDIS 6.x). When the connection is restored, it must then call **NdisM(Co)IndicateStatus** with NDIS_STATUS_MEDIA_CONNECT (for NDIS 5.1) or NDIS_STATUS_LINK_STATE with **MediaConnectStateConnected** in the MediaConnectState property (for NDIS 6.x).

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NdisMCoIndicateStatusEx

NdisMIndicateStatusEx

OID_GEN_MEDIA_CONNECT_STATUS_EX

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_CONNECT_STATUS_EX OID returns the connection state of an interface.

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

NDIS uses this OID to query the connection state of an NDIS network interface provider. Only NDIS interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the query succeeds, the interface provider returns NDIS_STATUS_SUCCESS, and the result of the query can be one of the values in the **NET_IF_MEDIA_CONNECT_STATE** enumeration.

Miniport drivers supply the media connect status during initialization and provide updates with status indications.

To specify the connection state in a miniport driver, set the **MediaConnectState** member of the **NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES** structure that the miniport driver passes to the **NdisMSetMiniportAttributes** function.

Requirements

Header	Ntddndis.h (include Ndis.h)

NDIS Network Interface OIDs

OID_GEN_MEDIA_DUPLEX_STATE

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_DUPLEX_STATE OID returns the duplex state of an interface.

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

NDIS uses this OID to query the duplex state of an NDIS network interface provider. Only NDIS interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the query succeeds, the interface provider returns NDIS_STATUS_SUCCESS, and the result of the query can be one of the values in the **NET_IF_MEDIA_DUPLEX_STATE** enumeration.

Miniport drivers supply the media duplex state during initialization and provide updates with status indications.

To specify the duplex state in a miniport driver, set the **MediaDuplexState** member of the **NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES** structure that the miniport driver passes to the **NdisMSetMiniportAttributes** function.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_MEDIA_IN_USE

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_IN_USE OID specifies a complete list of the media types that the NIC currently uses.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Obsolete.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

NDIS 6.0 and later miniport drivers do not receive this OID request. NDIS handles this OID with a cached value that miniport drivers supply during initialization.

This OID provides the same information as the OID_GEN_MEDIA_SUPPORTED OID.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_MEDIA_SUPPORTED

OID_GEN_MEDIA_SENSE_COUNTS

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_SENSE_COUNTS OID returns the number of times the miniport adapter reported a media state change.

Remarks

The OID_GEN_MEDIA_SENSE_COUNTS OID returns the number of times the miniport adapter reported a media state change.

Requirements

Version	Supported for NDIS 5.1 and later drivers in Windows Vista and later versions of Windows and later versions of Windows. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_MEDIA_SUPPORTED

Article • 02/18/2023

As a query, the OID_GEN_MEDIA_SUPPORTED OID specifies the media types that a NIC can support but not necessarily the media types that the NIC currently uses.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Obsolete.

The following media types were added for NDIS 6.0 and later drivers:

- **NdisMediumTunnel**
- **NdisMediumLoopback**
- **NdisMediumNative802_11**

The following media types were added for NDIS 6.20 and later drivers:

- **NdisMediumIP**

NDIS 5.1 miniport drivers
Mandatory. See OID_GEN_MEDIA_SUPPORTED (NDIS 5.1).

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory. See OID_GEN_MEDIA_SUPPORTED (NDIS 5.1).

Remarks

NDIS 6.0 and later miniport drivers do not receive this OID request. NDIS handles this OID with a cached value that miniport drivers supply during initialization.

These media types are listed as a proper subset of the following system-defined values:

NdisMedium802_3
Ethernet (802.3).

Note NDIS 5.*x* miniport drivers that conform to the 802.11 interface must use this media type. For more information about the 802.11 interface, see 802.11 Wireless LAN Miniport Drivers.

NdisMedium802_5
Token Ring (802.5). This media type is not supported for NDIS 6.0 and later drivers.

Note Starting with Windows 8, the operating system will not support this media type for any miniport drivers.

NdisMediumFddi
FDDI. This media type is not supported on Windows Vista and later versions of Windows.

NdisMediumWan
WAN

NdisMediumLocalTalk
LocalTalk

NdisMediumDix
DEC/Intel/Xerox (DIX) Ethernet

NdisMediumArcnetRaw
ARCNET (raw). This media type is not supported on Windows Vista and later versions of Windows.

NdisMediumArcnet878_2
ARCNET (878.2). This media type is not supported on Windows Vista and later versions of Windows.

NdisMediumAtm
ATM. This media type is not supported for NDIS 6.0 and later drivers.

NdisMediumNative802_11
Native 802.11. This media type is used by miniport drivers that conform to the Native 802.11 interface. For more information about this interface, see Native 802.11 Wireless LAN Miniport Drivers.

NdisMediumWirelessWan
Various types of **NdisWireless***Xxx* media. This media type is not available for use beginning with Windows Vista and later versions of Windows.

NdisMediumIrda
Infrared (IrDA).

NdisMediumCoWan
Connection-oriented WAN.

NdisMedium1394
IEEE 1394 (firewire) bus. This media type is not supported on Windows Vista and later versions of Windows.

NdisMediumBpc
Broadcast PC network.

NdisMediumInfiniBand
InfiniBand network.

NdisMediumTunnel
Tunnel network.

NdisMediumLoopback
NDIS loopback network.

NdisMediumIP
A generic medium that is capable of sending and receiving raw IP packets.

NDIS 5. *x* miniport drivers that support wireless LAN (WLAN) or wireless WAN (WWAN) packets appear to the operating system and to NDIS as Ethernet packets. These NDIS drivers must provide support for WWAN or WLAN networks as Ethernet networks. Such drivers declare their medium as **NdisMedium802_3** and emulate Ethernet to higher-level NDIS drivers. Such drivers must also declare in OID_GEN_PHYSICAL_MEDIUM the appropriate physical medium that they support..

For more information about NDIS 5.X WLAN miniport drivers, see 802.11 Wireless LAN Miniport Drivers.

NDIS 6.0 and later miniport drivers that support the WLAN media transfer packets that appear to the operating system and to NDIS as IEEE 802.11 packets. These NDIS drivers must provide support for WLAN networks as Native 802.11 miniport drivers. Such drivers declare their medium as **NdisMediumNative802_11**.

For more information about Native 802.11 miniport drivers, see Native 802.11 Wireless LAN Miniport Drivers.

If the underlying miniport driver returns **NULL** for this query, or if an experimental media type is used, the driver must indicate receive operations using the **NdisMIndicateReceiveNetBufferLists** function. Any protocol that is bound to such an underlying miniport driver receives all such indications, that is, the protocol driver cannot filter receive operations with OID_GEN_CURRENT_PACKET_FILTER.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_MINIPORT_RESTART_ATTRIBUTES

Article • 02/18/2023

The OID_GEN_MINIPORT_RESTART_ATTRIBUTES OID identifies general attributes for the propagation of miniport adapter restart attributes in an NDIS driver stack.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

Remarks

The OID_GEN_MINIPORT_RESTART_ATTRIBUTES OID is not used to issue OID query or set requests.

If the **Oid** member in the NDIS_RESTART_ATTRIBUTES structure is OID_GEN_MINIPORT_RESTART_ATTRIBUTES, the **Data** member of the structure contains an NDIS_RESTART_GENERAL_ATTRIBUTES structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

NDIS_RESTART_GENERAL_ATTRIBUTES

OID_GEN_MULTICAST_BYTES_RCV

Article • 02/18/2023

As a query, the OID_GEN_MULTICAST_BYTES_RCV OID specifies the number of bytes in multicast/functional packets that are received without errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_MULTICAST_BYTES_XMIT

Article • 02/18/2023

As a query, the OID_GEN_MULTICAST_BYTES_XMIT OID specifies the number of bytes in multicast/functional packets that are transmitted without errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_NETWORK_LAYER_ADDRESSES

Article • 02/18/2023

As a set, the OID_GEN_NETWORK_LAYER_ADDRESSES OID notifies underlying miniport driver and other layered drivers about the list of network-layer addresses that are associated with bound instances.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

A bound instance is the binding between the calling transport and a driver set up by a call to NdisOpenAdapterEx. Transports use TRANSPORT_ADDRESS and TA_ADDRESS structures to notify underlying miniport drivers and other layered drivers about the list of network-layer addresses. Miniport drivers and other layered drivers use compatible NETWORK_ADDRESS_LIST and NETWORK_ADDRESS structures, defined as follows, to set the list of network-layer addresses on a bound interface.

C++

```
typedef struct _NETWORK_ADDRESS_LIST {
  LONG  AddressCount;
  USHORT  AddressType;
  NETWORK_ADDRESS  Address[1];
} NETWORK_ADDRESS_LIST, *PNETWORK_ADDRESS_LIST;
```

The members of this structure contain the following information:

AddressCount
Specifies the number of network-layer addresses listed in the array in the **Address** member.

AddressType
Specifies the protocol type that sends this OID. This member is only valid if the **AddressCount** member is set to zero. The **AddressCount** member is set to zero to notify a miniport driver or other layered driver to clear the list of network-layer addresses on a bound interface. The protocol can be one of the following values:

NDIS_PROTOCOL_ID_DEFAULT
Default protocol

NDIS_PROTOCOL_ID_TCP_IP
TCP/IP protocol

NDIS_PROTOCOL_ID_IPX
NetWare IPX protocol

NDIS_PROTOCOL_ID_NBF
NetBIOS protocol

Address
Array of network-layer addresses of type NETWORK_ADDRESS. The **AddressCount** member specifies the number of elements in this array.

C++

```cpp
typedef struct _NETWORK_ADDRESS {
  USHORT  AddressLength;
  USHORT  AddressType;
  UCHAR   Address[1];
} NETWORK_ADDRESS, *PNETWORK_ADDRESS;
```

The members of this structure contain the following information:

AddressLength
Specifies the size, in bytes, of this network-layer address. The **Address** member contains the array of bytes that specify this address.

AddressType
Specifies the protocol type that sends this OID and this network-layer address. This member is only valid if the **AddressCount** member in the NETWORK_ADDRESS_LIST

structure is set to a nonzero value. The **AddressCount** member in NETWORK_ADDRESS_LIST is set to a nonzero value to notify a miniport driver or other layered driver to change the list of network-layer addresses on a bound interface. Protocol types are defined in the preceding list.

Address
Array of bytes that specify this network-layer address. The **AddressLength** member specifies the number of bytes in this array.

The transport can call the NdisOidRequest function and can pass an NDIS_OID_REQUEST structure that is filled with the OID_GEN_NETWORK_LAYER_ADDRESSES code. This call notifies a bound instance of a change in the addresses that are associated with that instance. In this call, the transport also passes the bound instance in the *NdisBindingHandle* parameter. The bound instance is the binding set up between the transport and the underlying miniport driver or other layered driver. For this call, the transport should fill the **InformationBuffer** member of NDIS_OID_REQUEST with a pointer to a TRANSPORT_ADDRESS structure. TRANSPORT_ADDRESS corresponds to a NETWORK_ADDRESS_LIST structure and should contain the list of network-layer addresses.

Suppose a transport passes addresses through an intermediate driver down to an underlying miniport driver. If the intermediate driver also requires the addresses, it should take note of them before passing them on to the underlying miniport driver. An underlying miniport driver, especially an old driver, can return a status value of NDIS_STATUS_NOT_SUPPORTED or NDIS_STATUS_SUCCESS. The underlying miniport driver propagates the status of the operation back up towards the transport. If the intermediate driver must continue receiving address notifications, and if it is necessary, the intermediate driver should change the status to NDIS_STATUS_SUCCESS.Otherwise, the transport might interpret NDIS_STATUS_NOT_SUPPORTED as an indication that the underlying miniport driver does not require that the transport issue additional address updates. If NDIS_STATUS_SUCCESS is returned, transports are obligated to continue notifying underlying drivers of any change in associated addresses, including addition and deletion of addresses.

A protocol can set the **AddressCount** member of TRANSPORT_ADDRESS to zero to notify a miniport driver or other layered driver to clear the list of network-layer addresses on a bound interface. If **AddressCount** is set to zero, the **AddressType** member in NETWORK_ADDRESS_LIST is valid and the **AddressType** members in NETWORK_ADDRESS structures are not valid. On the other hand, a protocol can set **AddressCount** to a nonzero value to notify a miniport driver or other layered driver to change the list of network-layer addresses on a bound interface. In this case, the

AddressType member in NETWORK_ADDRESS_LIST is not valid and the **AddressType** members in NETWORK_ADDRESS structures are valid.

NDIS_OID_REQUEST

NdisOidRequest

NdisOpenAdapterEx

OID_GEN_OPERATIONAL_STATUS

Article • 02/18/2023

As a query, use the OID_GEN_OPERATIONAL_STATUS OID to determine the current operational status of a network interface (*ifOperStatus* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

NDIS handles this OID for miniport adapters and filter modules, and only NDIS network interface providers receive this OID query.

If the query succeeds, the interface provider returns NDIS_STATUS_SUCCESS, and the result of the query can be one of the values in the **NET_IF_OPER_STATUS** enumeration.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NET_IF_OPER_STATUS

NDIS Network Interface OIDs

OID_GEN_PCI_DEVICE_CUSTOM_PROPERTIES

Article • 02/18/2023

As a query, overlying drivers use the OID_GEN_PCI_DEVICE_CUSTOM_PROPERTIES OID to get the PCI custom properties of a device.

Remarks

NDIS handles OID_GEN_PCI_DEVICE_CUSTOM_PROPERTIES and miniport drivers do not receive an OID query.

This query is optional for other NDIS drivers.

NDIS returns an NDIS_PCI_DEVICE_CUSTOM_PROPERTIES structure that contains the PCI custom properties.

For non-PCI miniport adapters, NDIS fails OID_GEN_PCI_DEVICE_CUSTOM_PROPERTIES with the NDIS_STATUS_INVALID_DEVICE_REQUEST status code.

Requirements

Version	Supported in NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_PCI_DEVICE_CUSTOM_PROPERTIES

OID_GEN_PHYSICAL_MEDIUM

Article • 02/18/2023

As a query, the OID_GEN_PHYSICAL_MEDIUM OID specifies the types of physical media that the NIC supports. This OID is essentially an extension of OID_GEN_MEDIA_SUPPORTED.

Version Information

Note This OID is supported in NDIS 6.0 and 6.1. For NDIS 6.20 and later, use OID_GEN_PHYSICAL_MEDIUM_EX.

Remarks

NDIS handles this OID for miniport drivers. The miniport driver supplies the physical medium value during initialization.

Miniport drivers report a physical media type to differentiate their physical media from media that they declared to support in the OID_GEN_MEDIA_SUPPORTED OID query. These media types are listed as a proper subset of the following system-defined values from the **NDIS_PHYSICAL_MEDIUM** enumeration:

NdisPhysicalMediumUnspecified The physical medium is none of the preceding mediums. For example, a one-way satellite feed is an unspecified physical medium.

NdisPhysicalMediumWirelessLan Packets are transferred over a wireless LAN network through a miniport driver that conforms to the 802.11 interface. For more information about this interface, see. 802.11 Wireless LAN Miniport Drivers

NdisPhysicalMediumCableModem Packets are transferred over a DOCSIS-based cable network.

NdisPhysicalMediumPhoneLine Packets are transferred over standard phone lines. Includes, for example, HomePNA media. **NdisPhysicalMediumPowerLine** Packets are transferred over wiring that is connected to a power distribution system.

NdisPhysicalMediumDSL Packets are transferred over a Digital Subscriber Line (DSL) network. Includes, for example, ADSL and UADSL (G.Lite).
NdisPhysicalMediumFibreChannel Packets are transferred over a Fibre Channel interconnect.

NdisPhysicalMedium1394 Packets are transferred over an IEEE 1394 bus.

NdisPhysicalMediumWirelessWan Packets are transferred over a Wireless WAN link. Includes, for example, CDPD, CDMA, and GPRS.

NdisPhysicalMediumNative802_11 Packets are transferred over a wireless LAN network through a miniport driver that conforms to the Native 802.11 interface. For more information about this interface, see Native 802.11 Wireless LAN Miniport Drivers.

Note The Native 802.11 interface is supported in NDIS 6.0 and later versions.

NdisPhysicalMediumBluetooth Packets are transferred over a Bluetooth network. Bluetooth is a short-range wireless technology that uses the 2.4 GHz spectrum.

NdisPhysicalMediumInfiniband The Infiniband physical medium. Packets are transferred over an infiniband interconnect.

NdisPhysicalMediumUWB The Ultra Wideband (UWB) physical medium. Packets are transferred over a UWB network. UWB is a radio frequency platform that personal area networks can use to wirelessly communicate over short distances at high speeds.

NdisPhysicalMedium802_3 The Ethernet (802.3) physical medium. Packets are transferred over a wired LAN through a miniport driver that conforms to the 802.3 interface specification. This medium type does not include devices that emulate 802.3.

NdisPhysicalMedium802_5 The Token Ring physical medium. (802.5 is not supported in NDIS 6.0 and later drivers.) Packets are transferred over a Token Ring network through a miniport driver that conforms to the 802.5 interface specification.

NdisPhysicalMediumIrda The infrared (IrDA) physical medium. Packets are transferred over a nonvisible, infrared light spectrum IrDA network.

NdisPhysicalMediumWiredWAN The wired, wide area network (WAN) physical medium. Packets are transferred over a wired WAN.

NdisPhysicalMediumWiredCoWan The wired, connection-oriented WAN physical medium. Packets are transferred over a wired WAN in a connection-oriented environment.

NdisPhysicalMediumOther The physical medium is none of the preceding mediums. **NdisPhysicalMediumOther** specifies a new physical medium type that is not present in the NDIS_PHYSICAL_MEDIUM enumeration.

NDIS supports the OID_GEN_PHYSICAL_MEDIUM OID for miniport adapters that support newer networks, even though those networks transfer packets that appear to the operating system and to NDIS as standard and well known media types.

Newer networks transfer packets that might appear like standard media but that might have new features or slight differences from the standard. This OID was developed so upper-layer drivers and applications could determine the actual networks to which a NIC connects. After retrieving information about underlying networks, upper-layer drivers and applications could use this information to modify how such drivers and applications behave.

To clearly distinguish an 802.3 NIC from an emulated 802.3 NIC for which there is no physical medium type defined, NDIS 6.0 and later versions require 802.3 miniport drivers to report **NdisPhysicalMedium802_3**.

Requirements

Version	Supported in NDIS 6.0 and 6.1. For NDIS 6.20 and later, use OID_GEN_PHYSICAL_MEDIUM_EX instead.
Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_MEDIA_SUPPORTED

OID_GEN_PHYSICAL_MEDIUM_EX

OID_GEN_PHYSICAL_MEDIUM_EX

Article • 02/18/2023

As a query, the OID_GEN_PHYSICAL_MEDIUM_EX OID specifies the types of physical media that a miniport adapter supports.

Remarks

NDIS handles this OID for NDIS 6.0 and later miniport drivers. The miniport driver supplies the physical medium value during initialization.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains an NDIS_PHYSICAL_MEDIUM enumeration value.

Note The difference between OID_GEN_PHYSICAL_MEDIUM_EX and OID_GEN_PHYSICAL_MEDIUM is that the OID_GEN_PHYSICAL_MEDIUM_EX version does not override the **NdisPhysicalMedium802_3** type as **NdisPhysicalMediumUnspecified** whereas OID_GEN_PHYSICAL_MEDIUM still does. We recommend that all 6.x drivers use the EX version. OID_GEN_PHYSICAL_MEDIUM_EX is exposed through a WMI GUID.

Miniport drivers report a physical media type to differentiate their physical media from media that they declared to support in the OID_GEN_MEDIA_SUPPORTED OID query.

NDIS supports the OID_GEN_PHYSICAL_MEDIUM_EX OID for miniport adapters that support newer networks, even though those networks transfer packets that appear to the operating system and to NDIS as standard, well-known media types.

Newer networks transfer packets that might appear like standard media, but that might have new features or slight differences from the standard. This OID exists so upper-layer drivers and applications can determine the actual networks to which a NIC connects. After retrieving information about underlying networks, upper-layer drivers and applications can use this information to modify how such drivers and applications behave.

To clearly distinguish an 802.3 NIC from an emulated 802.3 NIC for which there is no physical medium type defined, NDIS 6.0 and later and later versions require 802.3 miniport drivers to report an **NdisPhysicalMedium802_3** media type.

Requirements

Version	Supported in NDIS 6.20 and later. Not

	requested for miniport drivers. (See Remarks section.)
Header	Ntddndis.h (include Ndis.h)

OID_GEN_PORT_AUTHENTICATION_PARAMETERS

Article • 02/18/2023

As a set, NDIS and overlying drivers use the OID_GEN_PORT_AUTHENTICATION_PARAMETERS OID to set the current state of an NDIS port.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional. Mandatory for NDIS ports. (see Remarks section)

Remarks

Miniport drivers that support NDIS ports must support this OID.

If a miniport driver does not support this OID, the miniport driver should return NDIS_STATUS_NOT_SUPPORTED.

If the miniport driver supports this OID, the driver returns NDIS_STATUS_SUCCESS and provides the receive port direction, port control state, and authenticate state in an NDIS_PORT_AUTHENTICATION_PARAMETERS structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_PORT_AUTHENTICATION_PARAMETERS

OID_GEN_PORT_STATE

Article • 02/18/2023

As a query, overlying drivers use the OID_GEN_PORT_STATE OID to get the current state of the port that is specified in the **PortNumber** member of the NDIS_OID_REQUEST structure.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

NDIS handles this OID and miniport drivers do not receive this OID query.

If the query succeeds, NDIS returns NDIS_STATUS_SUCCESS and returns the port state information in an NDIS_PORT_STATE structure.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS_OID_REQUEST

NDIS_PORT_STATE

OID_GEN_PROMISCUOUS_MODE

Article • 02/18/2023

As a query, use the OID_GEN_PROMISCUOUS_MODE OID to determine whether a network interface is promiscuous or not (*ifPromiscuousMode* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the interface provider returns NDIS_STATUS_SUCCESS and if the interface accepts only packets that are addressed to that interface, the result value should be **FALSE**. This value should be **TRUE** if the interface accepts all network packets.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS Network Interface OIDs

OID_GEN_PROTOCOL_OPTIONS

Article • 02/18/2023

As a set, the OID_GEN_PROTOCOL_OPTIONS OID specifies a bitmask that defines optional properties of the protocol driver.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. This OID is for protocol drivers.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

A protocol informs NDIS of its properties, which can optionally take advantage of them. If the protocol driver does not set its flags on a binding, NDIS assumes they are all clear.

The following flags are currently defined:

NDIS_PROT_OPTION_ESTIMATED_LENGTH
Specifies that packets can be indicated at the worst-case estimate of packet size, instead of an exact value, to this protocol.

NDIS_PROT_OPTION_NO_LOOPBACK
Specifies that the protocol does not require loopback support on the binding.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_RCV_CRC_ERROR

Article • 02/18/2023

As a query, the OID_GEN_RCV_CRC_ERROR OID specifies the number of frames that are received with checksum errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

The value for the OID_GEN_RCV_DISCARDS OID includes CRC errors. For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_RCV_DISCARDS

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_RCV_DISCARDS OID to determine the number of receive discards on a miniport adapter.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

NDIS handles this OID for miniport drivers. See the OID_GEN_STATISTICS OID for more information about statistics.

The count is identical to the *ifInDiscards* counter described in RFC 2863.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_RCV_ERROR

Article • 02/18/2023

As a query, the OID_GEN_RCV_ERROR OID specifies the number of frames that a NIC receives but does not indicate to the protocols due to errors.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 drivers
Mandatory.

Remarks

The count is identical to the *ifInErrors* counter described in RFC 2863.

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_RCV_LINK_SPEED

Article • 02/18/2023

As a query, use the OID_GEN_RCV_LINK_SPEED OID to determine the receive link speed of a network interface.

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is a ULONG64 value that indicates the receive link speed of the interface, in bits per second.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS Network Interface OIDs

OID_GEN_RCV_NO_BUFFER

Article • 02/18/2023

As a query, the OID_GEN_RCV_NO_BUFFER OID specifies the number of frames that the NIC cannot receive due to lack of NIC receive buffer space. Some NICs do not provide the exact number of missed frames; they provide only the number of times at least one frame is missed.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 drivers
Mandatory.

Remarks

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_RCV_OK

Article • 02/18/2023

As a query, the OID_GEN_RCV_OK OID specifies the number of frames that the NIC receives without errors and indicates to bound protocols.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later drivers
Mandatory.

NDIS 5.1 drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 drivers
Mandatory.

Remarks

OID_GEN_RCV_OK specifies the number of frames that are received without errors. However, the OID_GEN_STATISTICS does not include this information.

NOTE: Statistics OIDs are mandatory for NDIS 6.0 and later miniport drivers unless NDIS handles them. For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_RECEIVE_BLOCK_SIZE

Article • 02/18/2023

As a query. the OID_GEN_RECEIVE_BLOCK_SIZE OID specifies the amount of storage, in bytes, that a single packet occupies in the receive buffer space of the NIC.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The OID_GEN_RECEIVE_BLOCK_SIZE OID specifies the amount of storage, in bytes, that a single packet occupies in the receive buffer space of a NIC.

The same information can be obtained from the current and maximum *lookahead* size. However, one of these OIDs can be mandatory to verify each other. Also protocol drivers can determine if the underlying driver indicates full-packet receives by comparing the values that driver returns for the OID_GEN_CURRENT_LOOKAHEAD and OID_GEN_RECEIVE_BLOCK_SIZE OIDs.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_CURRENT_LOOKAHEAD

OID_GEN_RECEIVE_BUFFER_SPACE

Article • 02/18/2023

As a query, the OID_GEN_RECEIVE_BUFFER_SPACE OID specifies the amount of memory on the NIC that is available for buffering receive data.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

A protocol driver can use this OID as a guide for advertising its receive window after it establishes sessions with remote nodes.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_RECEIVE_HASH

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_RECEIVE_HASH OID to obtain the current receive hash calculation settings of a miniport adapter. NDIS returns an NDIS_RECEIVE_HASH_PARAMETERS structure that contains the current receive hash settings.

As a set, NDIS and overlying drivers use the OID_GEN_RECEIVE_HASH OID to configure the receive hash calculations on a miniport adapter. The miniport driver receives an NDIS_RECEIVE_HASH_PARAMETERS structure.

Remarks

For NDIS miniport drivers, the query is not requested.

Support for this OID set is optional for miniport drivers, including those that support RSS.

An overlying driver can use the OID_GEN_RECEIVE_HASH OID to enable and configure hash calculations on received frames without enabling RSS.

Note Protocol drivers must disable receive hash calculations before they enable RSS. If RSS is enabled, a protocol driver disables RSS before it enables receive hash calculations. A miniport driver should fail a set request with **NDIS_STATUS_INVALID_OID** or **NDIS_STATUS_NOT_SUPPORTED** to enable receive hash calculations if OID_GEN_RECEIVE_SCALE_PARAMETERS is currently enabled.

Note The secret key is appended after the NDIS_RECEIVE_HASH_PARAMETERS structure members.

Requirements

Version	Supported in NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_RECEIVE_HASH_PARAMETERS

OID_GEN_RECEIVE_SCALE_CAPABILITIES

Article • 02/18/2023

As a query, overlying drivers can use the OID_GEN_RECEIVE_SCALE_CAPABILITIES OID to query the receive side scaling (RSS) capabilities of a NIC and its miniport driver.

Remarks

NDIS miniport drivers do not receive this OID request. NDIS handles the query for miniport drivers.

The miniport driver returns the RSS capabilities in an NDIS_RECEIVE_SCALE_CAPABILITIES structure.

Requirements

Version	Supported in NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_RECEIVE_SCALE_CAPABILITIES

OID_GEN_RECEIVE_SCALE_PARAMETERS

Article • 02/18/2023

As a query, NDIS and overlying drivers can use the OID_GEN_RECEIVE_SCALE_PARAMETERS OID to query the current receive side scaling (RSS) parameters of a NIC. NDIS returns an NDIS_RECEIVE_SCALE_PARAMETERS structure that defines the current RSS parameters.

As a set, NDIS and overlying drivers use the OID_GEN_RECEIVE_SCALE_PARAMETERS OID to set the current RSS parameters of a NIC. The miniport driver receives an NDIS_RECEIVE_SCALE_PARAMETERS structure that defines the RSS parameters.

> ⓘ **Note**
>
> In RSSv2, this OID is only used to query current RSS parameters of a given scaling entity. For miniport drivers that support RSSv2, see OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 for setting RSS parameters other than the indirection table.

Remarks

For NDIS miniport drivers, the query is not requested and the set is required for drivers that support RSS. NDIS handles the query for miniport drivers.

The TCP/IP driver configures IPv4 and IPv6 with a single OID set request of OID_GEN_RECEIVE_SCALE_PARAMETERS. That is, when the stack should enable RSS for both IPv4 and IPv6, it sets both of the corresponding flags in the **HashInformation** member of the NDIS_RECEIVE_SCALE_PARAMETERS structure and sends one OID request. Also, IPv4 and IPv6 use the same secret key and the key will always be 40 bytes, even if only IPv4 is enabled.

The underlying miniport adapter must use the most recent OID_GEN_RECEIVE_SCALE_PARAMETERS OID settings it has received. For example, if the miniport gets an OID_GEN_RECEIVE_SCALE_PARAMETERS OID with the IPv4 hash types missing, it must disable IPv4 RSS if it was previously enabled.

Note An overlying driver can use the OID_GEN_RECEIVE_HASH OID to enable and configure hash calculations on received frames without enabling RSS.

Note Protocol drivers must disable receive hash calculations (OID_GEN_RECEIVE_HASH) before they enable RSS. If RSS is enabled, a protocol driver disables RSS before it enables receive hash calculations. A miniport driver should fail a set request with **NDIS_STATUS_INVALID_OID** or **NDIS_STATUS_NOT_SUPPORTED** to enable RSS if OID_GEN_RECEIVE_HASH is currently enabled.

Note The indirection table and secret key are appended after the NDIS_RECEIVE_SCALE_PARAMETERS structure members. For more information about the indirection table and secret key, see **NDIS_RECEIVE_SCALE_PARAMETERS**.

Requirements

Version	Supported in NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_RECEIVE_HASH

OID_GEN_RECEIVE_SCALE_PARAMETERS_V2

Article • 02/18/2023

⚠ **Warning**

Some information in this topic relates to prereleased product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.

RSSv2 is preview only in Windows 10, version 1809.

The OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 OID is sent to RSSv2-capable miniport drivers to set run-time parameters, other than the indirection table, for a scaling entity. OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 replaces the OID_GEN_RECEIVE_SCALE_PARAMETERS OID from RSSv1 and is not visible to NDIS Light Weight Filters (LWFs) before NDIS 6.80. This OID is a Regular OID and can be issued as a Query or Set request. It is issued at IRQL == PASSIVE_LEVEL. It can target a given VPort, when the *NDIS_OID_REQUEST_FLAGS_VPORT_ID_VALID* flag is set at NIC switch creation. Otherwise, it targets the physical NIC in the Native RSS case.

As a Query, NDIS and overlying drivers can use OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 to query the RSS parameters of a NIC. NDIS returns an NDIS_RECEIVE_SCALE_PARAMETERS_V2 structure that defines the current RSS parameters.

As a Set, the purpose of this OID is to perform the following actions:

- Initially configure the scaling entity (a miniport adapter in Native RSS mode or a VPort in VMQ mode).
- Enable or disable RSS.
- When in RSS mode, perform non-timing-critical management functions such as changing the hash key, hash type and hash function, number of queues, or number of indirection table entries for the scaling entity.

Remarks

Enabling RSS and setting RSS parameters can be performed in one step.. After the upper layer enables RSS using this OID, the initial state of the scaling entity is as follows:

- The primary processor becomes *inactive*.
- The default processor becomes *active*.
- All the ITEs become *active*.
- The miniport driver starts calculation of the RSS hash, setting of the corresponding OOB for all packets, and directing packets to a processor specified by the indirection table entry or default processor parameter.

After RSS is enabled, the upper layer issues the OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES OID to move ITEs to different processors. In RSSv2, the **DefaultQueue** and **PrimaryProcessor** are also moved to a different processor using OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES.

During the process of disabling RSS, the upper layer will point all ITEs to the primary processor before invoking this OID to turn RSS off. After this point, receive traffic should target the primary processor. However, miniport drivers should not expect the disabling of RSS before VPort deletion. The upper layer can set the receive filter on the VPort to zero, thus ensuring that no receive traffic is flowing through the VPort, then proceed to delete the VPort without disabling RSS.

The upper layer will ensure that important invariants are not violated before performing management functions. For example:

- Before changing the number of queues, the upper layer will ensure that the indirection table does not reference more processors than configured for a VPort. Before changing the number of indirection table entries for VMMQ-RESTRICTED adapters, the upper layer will ensure that the content of the indirection table is normalized to the power of 2.

Error conditions and status codes

This OID returns the following status codes when an error occurs:

Status code	Error condition
NDIS_STATUS_INVALID_LENGTH	The OID was malformed.
NDIS_STATUS_NO_QUEUES	The number of queues is being changed when RSS is enabled, but the current indirection table references more processors than the new number of queues.

Status code	Error condition
NDIS_STATUS_INVALID_DATA	- The indirection table is being reduced in size, but does not contain a power-of-two repeat pattern. - During an RSS state transition (to *on* or *off*), a processor from a steering parameter that becomes *active* does not belong to the adapter's RSS processor set. Note that *inactive* steering parameters are only tracking writes to the processor and are not enforced. Enforcement happens during RSS state transition when the parameter becomes *active*.
NDIS_STATUS_INVALID_PARAMETER	Other fields, either in the header or the OID itself, contain invalid values.

Requirements

Version: Windows 10, version 1709 **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_RESET_COUNTS

Article • 02/18/2023

As a query, the OID_GEN_RESET_COUNTS OID returns the number of times the miniport adapter was reset.

Remarks

The OID_GEN_RESET_COUNTS OID returns the number of times the miniport adapter was reset.

Requirements

Version	Supported for NDIS 5.1 and later drivers in Windows Vista and later versions of Windows and later versions of Windows. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_GEN_RNDIS_CONFIG_PARAMETER

Article • 03/14/2023

As a set, the OID_GEN_RNDIS_CONFIG_PARAMETER is used to set device-specific parameters. The host uses it with RNDIS devices only.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For RNDIS devices only.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

The OID_GEN_RNDIS_CONFIG_PARAMETER is used with RNDIS devices. The host uses it to set device-specific parameters. It is not used by miniport drivers. For more information about this OID, see Setting Device-Specific Parameters.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES

Article • 02/18/2023

⚠ **Warning**

Some information in this topic relates to prereleased product, which may be substantially modified before it's commercially released. Microsoft makes no warranties, express or implied, with respect to the information provided here.

RSSv2 is preview only in Windows 10, version 1809.

The OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES OID is sent to RSSv2-capable miniport drivers to perform moves of individual indirection table entries. This OID is a Synchronous OID, meaning it cannot return NDIS_STATUS_PENDING. It is issued as a Method request only, at IRQL == DISPATCH_LEVEL.

This call uses the *XxxSynchronousOidRequest* entry point, where *Xxx* is either *Miniport* or *Filter* depending on the type of driver receiving the request. This entry point causes a system bug check if it sees an NDIS_STATUS_PENDING return status.

OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES uses the NDIS_RSS_SET_INDIRECTION_ENTRIES structure to instruct a miniport adapter to synchronously perform a set of actions, where each action moves a single entry of the RSS indirection table of a specified VPort to a target specified CPU.

Remarks

This OID must execute and complete in the processor context that issued it. Miniport drivers must fully execute this OID upon returning NDIS_STATUS_SUCCESS to the upper layer. This means that the miniport driver should be prepared to receive back-to-back OID requests to move multiple ITEs on a new processor immediately after the first move finishes with NDIS_STATUS_SUCCESS.

💡 **Tip**

Fully executing this OID means that the miniport driver must be ready to successfully attempt another action to move an ITE. It does not prescribe where in-flight receive traffic is indicated right after the queue move, which can either be on the source CPU or the target CPU.

Upper layer protocols issue OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES to set ITEs and/or the primary and default processor parameters to point to different processors.

This OID can be issued for either *active* or *inactive* traffic steering parameters. For more information about steering parameters, see Receive side scaling version 2 (RSSv2). For parameters/ITEs in the *inactive* state, the miniport driver should validate and cache the target processor until the next relevant RSS state change (enablement or disablement). At that point, cached processor numbers become *active* and are used for directing the traffic. Updates to *active* parameters (which must also be validated) should be taken immediately into effect to direct the traffic.

OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES must be issued to a miniport adapter with the *NDIS_OID_REQUEST_FLAGS_VPORT_ID_VALID* flag cleared. This is because of the possibility of different VPorts being referenced by different elements in the array.

This OID is invoked only at IRQL == DISPATCH_LEVEL.

Miniport drivers should be prepared to handle at least as many indirection table entry move actions as they advertise in the NDIS_NIC_SWITCH_CAPABILITIES structure. This is defined in the **NumberOfIndirectionTableEntriesPerNonDefaultVPort** or **NumberOfIndirectionTableEntriesForDefaultVPort** member of that structure, or **128** in Native RSS mode.

Miniport drivers should attempt to execute as many entries as they can and update the **EntryStatus** member of each NDIS_RSS_SET_INDIRECTION_ENTRY with the result of the operation.

OID handler for OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES

The OID handler for OID_GEN_RSS_SET_INDIRECTION_TABLE_ENTRIES is expected to behave as follows:

- A return of NDIS_STATUS_PENDING is not permitted due to the OID's Synchronous call type.
- Finalize any incoming ITE moves that were destined for the current CPU (previously initiated on remote processors).
- It is strongly recommended for miniport drivers to perform a full parameter validation pass. If not possible, perform one-by-one validation and execution of

array entries. Miniport drivers should specifically check if all the referenced objects are valid:

  - Returning NDIS_STATUS_PENDING in the **EntryStatus** field for an ITE is not permitted.
  - The miniport adapter exists and is in a good state. Else, set the **EntryStatus** field of the entry to NDIS_STATUS_ADAPTER_NOT_FOUND, NDIS_STATUS_ADAPTER_NOT_READY, etc.
  - Each VPort exists and is in a good state. Else, set the **EntryStatus** field of the entry to NDIS_STATUS_INVALID_PORT, NDIS_STATUS_INVALID_PORT_STATE, etc.
  - Each indirection table entry index is within the configured range. This range is either 0xFFFF or is in the [0...NumberOfIndirectionTableEntries - 1] range set by the OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 OID. The 0xFFFF and 0xFFFE entry indices have special meanings: 0xFFFF defines the default processor, while 0xFFFE defines the primary processor. On error, the handler sets the **EntryStatus** field of the entry to NDIS_STATUS_INVALID_PARAMETER.
  - The upper layer and the miniport driver expect that the ITE points to the current processor (actor CPU) before the move. In other words, the ITE cannot be redirected remotely. If this is not true, set the **EntryStatus** field of the entry to NDIS_STATUS_NOT_ACCEPTED.
  - All target processors are valid and are part of the miniport adapter's RSS set. Else, set the **EntryStatus** field of the entry to NDIS_STATUS_INVALID_DATA.

- Either subsequently or as part of the parameter validation pass, validate the resource situation. Validate that the number of queues to be used after a full batch move (evacuation) does not exceed the **NumberOfQueues** set in the NDIS_RECEIVE_SCALE_PARAMETERS_V2 structure during an OID_GEN_RECEIVE_SCALE_PARAMETERS_V2 request. Otherwise, NDIS_STATUS_NO_QUEUES is returned. NDIS_STATUS_NO_QUEUES should be used for all conditions that represent a violation of the configured number of queues. NDIS_STATUS_RESOURCES should only be used to designate transient out-of-memory conditions.
- As part of resource checks, for each scaling entity (for example, VPort), the miniport driver must handle a condition when all ITEs that point to the currrent CPU are moved away from it..

If all of the above checks pass, the miniport driver should be able to unconditionally apply the new configuration and must set the **EntryStatus** field of each entry to NDIS_STATUS_SUCCESS.

In general, the handler for this OID should be very light weight. It should not call NDIS or operating system services other than for possible synchronization operations like spinlocks and **NdisMConfigMSIXTableEntry**.

The miniport driver should not call NDIS to indicate status or PnP events.

The miniport driver should also not use receive/transmit complete indications in the context of this OID handler, as doing so leads to recursion. The upper layer can invoke this OID from the context of receive or transmit indications.

Moving all indirection table entries

Miniport drivers should recognize and handle a special request that moves all indirection table entries away from the current CPU. Because RSSv2 operates with individual ITE moves, miniport drivers must guarantee the atomicity of the overall operation. If it encounters an error in the middle of a batch while processing the corresponding array of move commands, the miniport driver should revert all commands that were already performed and mark all commands as "failed" in the per-command **EntryStatus** field. The upper layer protocol always expects the "move all ITEs" batch to contain either all commands marked as "succeeded," or all commands marked as "failed," and it will assume that traffic obeys the resulting state (either before or after the move). If the upper layer sees only some entries marked as "failed," it will bug check the system and point to the miniport driver as the cause.

To aid the miniport driver's handling of the "move all ITEs" command, and to avoid deadlocks, upper layer protocols group move commands in the batch in pairs of **SwitchId** + **VPortId** fields, such that:

- Commands that the upper layer wants to be executed together, as part of the "move all" command, for the same VPort are placed consecutively in the overall batch.
- The miniport driver should not attempt to execute the overall command batch, which may target different VPorts, in a "move all" fashion. Only the group of commands that target the same VPort (tagged with the same **SwitchId** + **VPortId** pair) need to be executed conforming to the "move all" semantics.
- When the upper layer does not care about "move all" semantics, it might interleave commands to the same VPort with commands to different VPort(s). In this case, if the second group of commands to the same VPort can't be executed because of a "number of queues" violation, the miniport driver marks that group with the corresponding status code (NDIS_STATUS_NO_QUEUES) and the upper layer takes responsibility for recovering.

For example, if the upper layer protocol interleaves a series of commands like this:

- `VPort=1 ITE[0,1]`
- `VPort=2 ITE[0]`

- `VPort=1 ITE[2]`

The miniport driver does not need to attempt to atomically execute all four move commands, or all three move commands for `VPort=1` (`ITE[0,1,2]`). It only needs to execute the `VPort=1 ITE[0,1]` group in a "move all" fashion, then the `VPort=2 ITE[0]` group, then `VPort=1 ITE[2]`. All three command groups might have a different outcome. For example, the groups for `VPort=1 ITE[0,1]` and `VPort=2 ITE[0]` might succeed, and the `VPort=1 ITE[2]` group might fail. The outcome should be reflected in the corresponding **EntryStatus** member of each command structure. This way, the miniport driver does not need to take precautions for safe execution of the overall batch (for example, lock the whole adapter). Only those commands that target a specific VPort need to be serialized, finer-grained per-VPort locking can be used, and certain deadlocks are avoided.

> ⓘ Note
>
> The entire group of the command entries must be marked with the same entry status.

Error conditions and status codes

This OID returns the following status codes when an error occurs:

Status code	Error condition
NDIS_STATUS_INVALID_LENGTH	The OID was malformed.
NDIS_STATUS_INVALID_PARAMETER	Other fields, either in the header or in the OID itself (but not in individual command entries) contain invalid values.

Requirements

Version: Windows 10, version 1709 **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_STATISTICS

Article • 02/06/2024

As a query, NDIS and overlying drivers use the OID_GEN_STATISTICS OID to obtain statistics of an adapter or a miniport driver.

Note: General statistics OIDs count all traffic through the network adapter including Network Direct Kernel (NDK) traffic. NDK statistics may be counted separately with OID_NDK_STATISTICS.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

The NDIS_STATISTICS_INFO structure is defined as follows:

ManagedCPlusPlus

```
    typedef struct _NDIS_STATISTICS_INFO {
         NDIS_OBJECT_HEADER Header;
         ULONG SupportedStatistics;
         ULONG64 ifInDiscards;
         ULONG64 ifInErrors;
         ULONG64 ifHCInOctets;
         ULONG64 ifHCInUcastPkts;
         ULONG64 ifHCInMulticastPkts;
         ULONG64 ifHCInBroadcastPkts;
         ULONG64 ifHCOutOctets;
         ULONG64 ifHCOutUcastPkts;
         ULONG64 ifHCOutMulticastPkts;
         ULONG64 ifHCOutBroadcastPkts;
         ULONG64 ifOutErrors;
         ULONG64 ifOutDiscards;
         ULONG64 ifHCInUcastOctets;
         ULONG64 ifHCInMulticastOctets;
         ULONG64 ifHCInBroadcastOctets;
         ULONG64 ifHCOutUcastOctets;
         ULONG64 ifHCOutMulticastOctets;
         ULONG64 ifHCOutBroadcastOctets;
    } NDIS_STATISTICS_INFO, *PNDIS_STATISTICS_INFO;
```

This structure contains the following members:

Header
The NDIS_OBJECT_HEADER structure for the NDIS_STATISTICS_INFO structure. Set the **Type** member of the structure that **Header** specifies to NDIS_OBJECT_TYPE_DEFAULT, the **Revision** member to NDIS_STATISTICS_INFO_REVISION_1, and the **Size** member to NDIS_SIZEOF_STATISTICS_INFO_REVISION_1.

SupportedStatistics
The set of statistics that the miniport driver supports.

Note NDIS 6.0 and later drivers must support all statistics and must report them when queried for OID_GEN_STATISTICS.

The value is the bitwise OR of the following flags:

NDIS_STATISTICS_FLAGS_VALID_DIRECTED_FRAMES_RCV
The data in the **ifHCInUcastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_MULTICAST_FRAMES_RCV
The data in the **ifHCInMulticastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BROADCAST_FRAMES_RCV
The data in the **ifHCInBroadcastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BYTES_RCV
The data in the **ifHCInOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_RCV_DISCARDS
The data in the **ifInDiscards** member is valid.

NDIS_STATISTICS_FLAGS_VALID_RCV_ERROR
The data in the **ifInErrors** member is valid.

NDIS_STATISTICS_FLAGS_VALID_DIRECTED_FRAMES_XMIT
The data in the **ifHCOutUcastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_MULTICAST_FRAMES_XMIT
The data in the **ifHCOutMulticastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BROADCAST_FRAMES_XMIT
The data in the **ifHCOutBroadcastPkts** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BYTES_XMIT
The data in the **ifHCOutOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_XMIT_ERROR
The data in the **ifOutErrors** member is valid.

NDIS_STATISTICS_FLAGS_VALID_XMIT_DISCARDS
The data in the **ifOutDiscards** member is valid.

NDIS_STATISTICS_FLAGS_VALID_DIRECTED_BYTES_RCV
The data in the **ifHCInUcastOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_MULTICAST_BYTES_RCV
The data in the **ifHCInMulticastOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BROADCAST_BYTES_RCV
The data in the **ifHCInBroadcastOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_DIRECTED_BYTES_XMIT
The data in the **ifHCOutUcastOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_MULTICAST_BYTES_XMIT
The data in the **ifHCOutMulticastOctets** member is valid.

NDIS_STATISTICS_FLAGS_VALID_BROADCAST_BYTES_XMIT
The data in the **ifHCOutBroadcastOctets** member is valid.

ifInDiscards
The dropped-receive-buffer error count. This is the same value that OID_GEN_RCV_DISCARDS returns.

ifInErrors
The receive error count. This count is the same value that OID_GEN_RCV_ERROR returns.

ifHCInOctets
The sum of the receive-directed byte count, receive-multicast byte count, and receive-broadcast byte count. This sum is the same value that OID_GEN_BYTES_RCV returns.

ifHCInUcastPkts
The number of directed packets that are received without errors. This number is the same value that OID_GEN_DIRECTED_FRAMES_RCV returns.

ifHCInMulticastPkts
The number of multicast/functional packets that are received without errors. This number is the same value that OID_GEN_MULTICAST_FRAMES_RCV returns.

ifHCInBroadcastPkts
The number of broadcast packets that are received without errors. This number is the same value that OID_GEN_BROADCAST_FRAMES_RCV returns.

ifHCOutOctets
The sum of the transmit-directed byte count, transmit-multicast byte count and transmit-broadcast byte count. This sum is the same value that OID_GEN_BYTES_XMIT returns.

ifHCOutUcastPkts
The number of directed packets that are transmitted without errors. This number is the same value that OID_GEN_DIRECTED_FRAMES_XMIT returns.

ifHCOutMulticastPkts
The number of multicast/functional packets that are transmitted without errors. This number is the same value that OID_GEN_MULTICAST_FRAMES_XMIT returns.

ifHCOutBroadcastPkts
The number of broadcast packets that are transmitted without errors. This number is the same value that OID_GEN_BROADCAST_FRAMES_XMIT returns.

ifOutErrors
The transmit error count. This count is the same value that OID_GEN_XMIT_ERROR returns.

ifOutDiscards
The number of packets that is discarded by the interface. This is same as the value that is returned by querying the OID_GEN_XMIT_DISCARDS OID.

ifHCInUcastOctets
The number of bytes in directed packets that are received without errors. This count is the same value that OID_GEN_DIRECTED_BYTES_RCV returns.

ifHCInMulticastOctets
The number of bytes in multicast/functional packets that are received without errors. This count is the same value that OID_GEN_MULTICAST_BYTES_RCV returns.

ifHCInBroadcastOctets
The number of bytes in broadcast packets that are received without errors. This count is the same value that OID_GEN_BROADCAST_BYTES_RCV returns.

ifHCOutUcastOctets
The number of bytes in directed packets that are transmitted without errors. This count is the same value that OID_GEN_DIRECTED_BYTES_XMIT returns.

ifHCOutMulticastOctets
The number of bytes in multicast/functional packets that are transmitted without errors. This count is the same value that OID_GEN_MULTICAST_BYTES_XMIT returns.

ifHCOutBroadcastOctets
The number of bytes in broadcast packets that are transmitted without errors. This count is the same value that OID_GEN_BROADCAST_BYTES_XMIT returns.

Remarks

Miniport drivers must implement the statistics counters and report the correct statistics values. The statistics counters are unsigned 64-bit values. The miniport driver returns the statistics in an NDIS_STATISTICS_INFO structure.

OID_GEN_SUPPORTED_GUIDS

Article • 02/18/2023

As a query, the OID_GEN_SUPPORTED_GUIDS OID requests the miniport driver to return an array of structures of the type NDIS_GUID.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

Each structure in the array specifies the mapping of a custom GUID (globally unique identifier) to either a custom OID or to an NDIS_STATUS that the miniport driver sends through the NdisMIndicateStatusEx function.

The NDIS_GUID structure is defined as follows:

C++

```
typedef struct _NDIS_GUID {
    GUID                Guid;
    union {
        NDIS_OID        Oid;
        NDIS_STATUS     Status;
    };
    ULONG               Size;
    ULONG               Flags;
} NDIS_GUID, *PNDIS_GUID;
```

The members of this structure contain the following information:

Guid
Specifies the custom GUID defined for the miniport driver.

Oid
Specifies the custom OID to which **Guid** maps.

Status
Specifies the NDIS_STATUS to which **Guid** maps.

Size
Specifies the size in bytes of each data item in the array returned by the miniport driver. If the fNDIS_GUID_ANSI_STRING or fNDIS_GUID_NDIS_STRING flag is set, **Size** is set to -1. Otherwise, **Size** specifies the size in bytes of the data item that the GUID represents. This member is specified only when the fNDIS_GUID_ARRAY flag is set.

Flags
The following flags can be combined by the OR operator to indicate whether the GUID maps to an OID or to an NDIS_STATUS string and to indicate the type of data that is supplied for the GUID:

fNDIS_GUID_TO_OID
Indicates that the NDIS_GUID structure maps a GUID to an OID.

fNDIS_GUID_TO_STATUS
Indicates that the NDIS_GUID structure maps a GUID to an NDIS_STATUS string.

fNDIS_GUID_ANSI_STRING
Indicates that a null-terminated ANSI string is supplied for the GUID.

fNDIS_GUID_UNICODE_STRING
Indicates that a Unicode string is supplied for the GUID.

fNDIS_GUID_ARRAY
Indicates that an array of data items is supplied for the GUID. The specified **Size** indicates the length of each data item in the array.

fNDIS_GUID_ALLOW_READ
When set, indicates that all users are allowed to use this GUID to obtain information.

fNDIS_GUID_ALLOW_WRITE
When set, indicates that all users are allowed to use this GUID to set information.

Note By default, custom WMI GUIDs supplied by a miniport driver are only accessible to users with administrator privileges. A user with administrator privileges can always read or write to a custom GUID if the miniport driver supports the read or write operation for that GUID. Set the fNDIS_GUID_ALLOW_READ and fNDIS_GUID_ALLOW_WRITE flags to allow all users to access a custom GUID.

Note that all custom GUIDs registered by a miniport driver must set either fNDIS_GUID_TO_OID or fNDIS_GUID_TO_STATUS (never set both). All other flags may be combined by using the OR operator as applicable.

In the following example, an NDIS_GUID structure maps a GUID to OID_802_3_MULTICAST_LIST:

C++

```
NDIS_GUID    NdisGuid = {{0x44795701, 0xa61b, 0x11d0, 0x8d, 0xd4,
                          0x00, 0xc0, 0x4f, 0xc3,
                          0x35, 0x8c},
                          OID_802_3_MULTICAST_LIST,
                          6,
                          fNDIS_GUID_TO_OID | fNDIS_GUID_ARRAY};
```

A GUID is an identifier used by Windows Management Instrumentation (WMI) to obtain or set information. NDIS intercepts a GUID sent by WMI to an NDIS driver, it maps the GUID to an OID, and sends the OID to the driver. The driver returns the data items to NDIS, which then returns the data to WMI.

NDIS also translates changes in NIC status into GUIDs that are recognized by WMI. When a miniport driver reports a change in NIC status using the NdisMIndicateStatusEx function, NDIS translates the NDIS_STATUS indicated by the miniport driver into a GUID that NDIS sends to WMI.

If a miniport driver supports customs GUIDs, it must support OID_GEN_SUPPORTED_GUIDS. This OID returns to NDIS the mapping of custom GUIDs to custom OIDs or NDIS_STATUS strings. After querying the miniport driver using OID_GEN_SUPPORTED_GUIDS, NDIS registers the miniport driver's custom GUIDs with WMI.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NdisMIndicateStatusEx

OID_GEN_SUPPORTED_LIST

Article • 02/18/2023

As a query, the OID_GEN_SUPPORTED_LIST OID specifies an array of OIDs for objects that the miniport driver or a NIC supports. Objects include general, media-specific, and implementation-specific objects.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested.

NDIS 5.1 miniport drivers
Mandatory. See OID_GEN_SUPPORTED_LIST (NDIS 5.1).

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory. See OID_GEN_SUPPORTED_LIST (NDIS 5.1).

Remarks

NDIS 6.0 and later miniport drivers do not receive this OID request. NDIS handles this OID with a cached value that miniport drivers supply during initialization.

To specify the list of supported OIDs during initialization, a miniport driver sets the **SupportedOidList** member of the **NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES** structure and passes the structure to the **NdisMSetMiniportAttributes** function.

NDIS forwards a subset of the provided list to protocol drivers that make this query. That is, NDIS filters any supported statistics OIDs out of the list because protocol drivers never make statistics queries.

If a miniport driver lists an OID in its supported OIDs list, it must fully support the OID. That is, the miniport driver must return valid data when it responds to a query or set request for the OIDs that it includes in the list. For example, the OID_GEN_STATISTICS OID is a required OID for NDIS 6.0 and later miniport drivers. If a miniport driver does not support the statistics in hardware or software and returns incorrect statistics information, the driver cannot specify OID_GEN_STATISTICS in its supported OIDs list.

Duplicates might appear in the supported OIDs list. Drivers are not required to guarantee that there is only one entry for each OID in the list.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_TRANSMIT_BLOCK_SIZE

Article • 02/18/2023

As a query, the OID_GEN_TRANSMIT_BLOCK_SIZE OID specifies the minimum number of bytes that a single net packet occupies in the transmit buffer space of the NIC.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The OID_GEN_TRANSMIT_BLOCK_SIZE OID specifies the minimum number of bytes that a single net packet occupies in the transmit buffer space of the NIC. For example, a NIC that has a transmit space divided into 256-byte pieces would have a transmit block size of 256 bytes. To calculate the total transmit buffer space on such a NIC, its driver multiplies the number of transmit buffers on the NIC by its transmit block size.

For other NICs, the transmit block size is identical to its maximum packet size.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_TRANSMIT_BUFFER_SPACE

Article • 02/18/2023

As a query, the OID_GEN_TRANSMIT_BUFFER_SPACE OID specifies the amount of memory, in bytes, on the NIC that is available for buffering transmit data.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

A protocol can use this OID as a guide for sizing the amount of transmit data per send.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_TRANSMIT_QUEUE_LENGTH

Article • 02/18/2023

As a query, the OID_GEN_TRANSMIT_QUEUE_LENGTH OID specifies the number of packets that are currently queued for transmission, whether on the NIC or in a driver-internal queue.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later drivers
Optional.

NDIS 5.1 drivers
Optional.

Windows XP
Supported.

NDIS 5.1 drivers
Optional.

Remarks

For queries, the number returned is always the total number of packets currently queued. This number can include unsubmitted send requests queued in the NDIS library.

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_TRANSPORT_HEADER_OFFSET

Article • 02/18/2023

As a set, the OID_GEN_TRANSPORT_HEADER_OFFSET OID indicates the size of additional headers for packets that a particular transport sends and receives.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

A transport informs miniport drivers and other layered drivers of this header size; these drivers can then use this information when processing packets. For example, a driver could use the sublayer header size obtained from the transport to locate the beginning of higher layer information in packets, such as the start of the IP header; the driver could then parse and adjust the fields of the IP protocol header as appropriate. Transports use a TRANSPORT_HEADER_OFFSET structure, defined as follows, to indicate this header size.

C++

```
typedef struct _TRANSPORT_HEADER_OFFSET {
  USHORT  ProtocolType;
  USHORT  HeaderOffset;
} TRANSPORT_HEADER_OFFSET, *PTRANSPORT_HEADER_OFFSET;
```

The members of this structure contain the following information:

ProtocolType
Specifies the protocol type that sends this OID and that subsequently sends and receives packets using the specified sublayer header size. The protocol is one of the following values:

NDIS_PROTOCOL_ID_DEFAULT
Default protocol

NDIS_PROTOCOL_ID_TCP_IP
TCP/IP protocol

NDIS_PROTOCOL_ID_IPX
NetWare IPX protocol

NDIS_PROTOCOL_ID_NBF
NetBIOS protocol

HeaderOffset
Specifies the size, in bytes, of the sublayer header that precedes the protocol header for packets that the protocol subsequently sends to or receives from the miniport driver or other layered driver. For example, sizeof(Ethernet header) + sizeof(SNAP header).

Typically, transports calculate the header size of packets from information that is retrieved from miniport drivers. To request the maximum total packet size in bytes that a NIC supports, including the header, transports use the OID_GEN_MAXIMUM_TOTAL_SIZE OID. To request the maximum packet size in bytes that a NIC supports, not including a header, transports use the OID_GEN_MAXIMUM_FRAME_SIZE OID. To calculate the maximum header size, transports subtract the maximum frame size from the maximum total size.

If a transport transmits packets that contain sublayer header information, the transport must know the sublayer header size of these packets and must inform underlying miniport drivers and other layered drivers about the size so that the drivers can process the packets. Sending and receiving particular sublayer header information within a packet may be an option that can be set in the registry for a particular protocol. Transports could then obtain information about sublayer headers from the registry and pass the header size down to miniport drivers or other layered drivers.

For example, if a transport handles packets from the Fiber Distributed Data Interface medium, the transport must send a set request to underlying miniport drivers and other layered drivers using OID_GEN_TRANSPORT_HEADER_OFFSET to inform those drivers about the size of the packets' sublayer header. (FDDI is not supported in Windows Vista and later versions of Windows.) These packets from FDDI could contain Logical Link

Control (LLC) information. This LLC information could in turn include an LLC header and other headers such as Sub-Network Access Protocol (SNAP). The transport determines from the registry to use LLC/SNAP and passes the header size of the LLC/SNAP segments of packets to miniport drivers.

This OID is optional for miniport drivers and other layered drivers. Because this OID is optional, drivers are not required to respond to requests that transports make using this OID.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_MAXIMUM_FRAME_SIZE

OID_GEN_MAXIMUM_TOTAL_SIZE

OID_GEN_UNKNOWN_PROTOS

Article • 02/18/2023

As a query, use the OID_GEN_UNKNOWN_PROTOS OID to determine the unknown-protocol packet count of a network interface (*ifInUnknownProtos* from RFC 2863).

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

The unknown-protocol statistics counter specifies the number of packets that were received through the interface that were discarded because the associated protocol was unknown or unsupported.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is a ULONG64 value that specifies the number of packets.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS Network Interface OIDs

OID_GEN_VENDOR_DESCRIPTION

Article • 02/18/2023

As a query, the OID_GEN_VENDOR_DESCRIPTION OID points to a null-terminated Unicode string describing the Network Interface Controller (NIC).

Set requests are not supported.

Remarks

This OID is mandatory for NDIS 6.0 and later miniport drivers.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_VENDOR_DRIVER_VERSION

Article • 02/18/2023

As a query, the OID_GEN_VENDOR_DRIVER_VERSION OID specifies the vendor-assigned version number of the miniport driver.

Set requests are not supported.

Remarks

The low-order half of the return value specifies the minor version; the high-order half specifies the major version.

This OID is mandatory for NDIS 6.0 and later miniport drivers.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_GEN_VENDOR_ID

Article • 02/18/2023

As a query, the OID_GEN_VENDOR_ID OID specifies a three-byte IEEE-registered vendor code, followed by a single byte that the vendor assigns to identify a particular NIC.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Mandatory.

NDIS 5.1 miniport drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Mandatory.

Remarks

The IEEE code uniquely identifies the vendor and is the same as the three bytes appearing at the beginning of the NIC hardware address.

Vendors without an IEEE-registered code should use the value 0xFFFFFF.

Independent hardware vendor's filter drivers or intermediate drivers might query this OID.

Requirements

Header	Ntddndis.h (include Ndis.h)

OID_GEN_VLAN_ID

Article • 02/18/2023

As a query, the OID_GEN_VLAN_ID OID reports the configured VLAN identifier (ID) for a NIC.

As a set, the OID_GEN_VLAN_ID OID specifies the configured VLAN identifier (ID) for an NIC that the miniport driver handles.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Optional.

NDIS 5.1 miniport drivers
Optional.

Windows XP
Supported.

NDIS 5.1 miniport drivers
Optional.

Remarks

The information buffer passed in this request contains an NDIS_VLAN_ID data type. This NDIS_VLAN_ID value contains the VLAN ID in the 12 least significant bits per the IEEE 802.1Q-2005 standard. Higher order bits of the NDIS_VLAN_ID value are reserved and must be set to 0. Note that NDIS defines NDIS_VLAN_ID as a ULONG.

When a transport uses OID_GEN_VLAN_ID in a query, the miniport driver returns the current configured VLAN ID for the NIC. When used in a set, the miniport driver sets the NIC's current configured VLAN ID to the specified value.

During the miniport driver's *MiniportInitializeEx* function for a particular NIC, the driver initially sets the NIC's VLAN ID to zero. The driver's *MiniportInitializeEx* function then reads the following configuration parameter from the registry, and, if the parameter is present, sets the NIC's VLAN ID to the parameter's value.

syntax

```
VlanId, REG_DWORD
```

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

MiniportInitializeEx

OID_GEN_XMIT_DISCARDS

Article • 02/18/2023

As a query, NDIS and overlying drivers use the OID_GEN_XMIT_DISCARDS OID to determine the number of transmit discards on a miniport adapter.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later miniport drivers
Not requested. (see Remarks section)

Remarks

NDIS handles this OID for miniport drivers. See the OID_GEN_STATISTICS OID for more information about statistics.

The count that this OID returns is the number of packets that is discarded by the interface. The count is identical to the *ifOutDiscards* counter described in RFC 2863.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_XMIT_ERROR

Article • 02/18/2023

As a query, the OID_GEN_XMIT_ERROR OID specifies the number of frames that a NIC fails to transmit.

Version Information

Windows Vista and later versions of Windows
Obsolete.

NDIS 6.0 and later drivers
Not requested. Use OID_GEN_STATISTICS instead.

NDIS 5.1 drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 drivers
Mandatory.

Remarks

The count is identical to the *ifOutErrors* counter described in RFC 2863.

For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_GEN_XMIT_LINK_SPEED

Article • 02/18/2023

As a query, use the OID_GEN_XMIT_LINK_SPEED OID to determine the transmit link speed of a network interface.

Version Information

Windows Vista and later
Supported.

NDIS 6.0 and later miniport drivers
Not requested. For NDIS interface providers only.

Remarks

Only NDIS network interface providers, and therefore not miniport drivers or filter drivers, must support this OID as an OID request.

If the interface provider returns NDIS_STATUS_SUCCESS, the result of the query is a ULONG64 value that indicates the transmit link speed of the interface, in bits per second.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

NDIS Network Interface OIDs

OID_GEN_XMIT_OK

Article • 02/18/2023

As a query, the OID_GEN_XMIT_OK OID specifies the number of frames that are transmitted without errors.

Version Information

Windows Vista and later versions of Windows
Supported.

NDIS 6.0 and later drivers
Mandatory.

NDIS 5.1 drivers
Mandatory.

Windows XP
Supported.

NDIS 5.1 drivers
Mandatory.

Remarks

OID_GEN_XMIT_OK specifies the number of frames that are transmitted without errors. However, the OID_GEN_STATISTICS does not include this information.

NOTE: Statistics OIDs are mandatory for NDIS 6.0 and later miniport drivers unless NDIS handles them. For general information about statistics OIDs, see General Statistics.

Requirements

Header	Ntddndis.h (include Ndis.h)

See also

OID_GEN_STATISTICS

OID_IP4_OFFLOAD_STATS

Article • 02/18/2023

The host stack queries the OID_IP4_OFFLOAD_STATS OID to obtain statistics on IPv4 datagrams that an offload target has processed on offloaded TCP connections. The host stack sets this OID to cause an offload target to reset the counters for such statistics to zero.

In response to a query of OID_IP4_OFFLOAD_STATS, an offload target supplies a filled-in IP_OFFLOAD_STATS structure. The IP_OFFLOAD_STATS structure contains the statistics for IPv4 datagrams processed on offloaded TCP connections.

In response to a set of OID_IP4_OFFLOAD_STATS, an offload target should reset all of its IPv4 statistics counters for offloaded TCP connections to zero.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_IP6_OFFLOAD_STATS

Article • 02/18/2023

The host stack queries the OID_IP6_OFFLOAD_STATS OID to obtain statistics on IPv6 datagrams that an offload target has processed on offloaded TCP connections. The host stack sets this OID to cause an offload target to reset the counters for such statistics to zero.

In response to a query of OID_IP6_OFFLOAD_STATS, an offload target supplies a filled-in IP_OFFLOAD_STATS structure. The IP_OFFLOAD_STATS structure contains the statistics for IPv6 datagrams processed on offloaded TCP connections.

In response to a set of OID_IP6_OFFLOAD_STATS, an offload target should reset all of its IPv6 statistics counters for offloaded TCP connections to zero.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_NDK_CONNECTIONS

Article • 02/18/2023

As a query, NDIS and overlying drivers or user-mode applications use the OID_NDK_CONNECTIONS OID to query the list of active Network Direct connections from the miniport adapter.

NDIS 6.30 and later miniport drivers that provide NDK services must support this OID. Otherwise, this OID is optional.

Remarks

NDIS issues this OID to obtain the list of active Network Direct connections from an adapter. The adapter must return the list of connections with the NDIS_NDK_CONNECTIONS structure at the **InformationBuffer** member of the NDIS_OID_REQUEST structure.

This structure is variable-sized based on the number of connections that are returned. The size of the connection array, as element count, is specified in the **Count** member.

Requirements

Minimum supported client	None supported
Minimum supported server	Windows Server 2012
Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_NDK_CONNECTIONS

NDIS_OID_REQUEST

OID_NDK_LOCAL_ENDPOINTS

Article • 02/18/2023

As a query, NDIS and overlying drivers or user-mode applications use the OID_NDK_LOCAL_ENDPOINTS OID to the list of active Network Direct listeners and shared endpoints on a miniport adapter.

NDIS 6.30 and later miniport drivers that provide NDK services must support this OID. Otherwise, this OID is optional.

Remarks

NDIS issues this OID to obtain the list of active Network Direct listeners and shared endpoints from an adapter. The adapter is required to return the list of listeners and shared endpoints in the NDIS_NDK_LOCAL_ENDPOINTS structure at **InformationBuffer** member of the NDIS_OID_REQUEST structure.

This structure is variable-sized based on the number of local endpoints that are returned. The size of the local endpoint array, as element count, is specified in the **Count** member.

Requirements

Minimum supported client	None supported
Minimum supported server	Windows Server 2012
Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_NDK_LOCAL_ENDPOINTS

NDIS_OID_REQUEST

OID_NDK_SET_STATE

Article • 02/18/2023

As a set request, NDIS and overlying drivers use the OID_NDK_SET_STATE OID to set the state of the miniport adapter's NDK functionality.

NDIS 6.30 and later miniport drivers that provide NDK services must support this OID. Otherwise, this OID is optional.

Remarks

NDIS issues this OID with the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure pointing to a **BOOLEAN** and **InformationBufferLength** member equal to sizeof(**BOOLEAN**).

- If the **BOOLEAN** value is **TRUE** and the ***NetworkDirect** keyword value is nonzero, the miniport adapter's NDK functionality must be enabled.

  The miniport driver can read the ***NetworkDirect** keyword value by doing the following:

  1. Call **NdisOpenConfigurationEx** with the NDIS handle that the **NdisMRegisterMiniportDriver** function returned when the miniport driver was initialized. For more information about calling **NdisOpenConfigurationEx**, see Reading the Registry in an NDIS 6.0 Miniport Driver.

  2. Call **NdisReadConfiguration**, passing:

     - "*NetworkDirect" for the *Keyword* parameter

     - **NdisParameterInteger** for the *ParameterType* parameter

- If the **BOOLEAN** value is **FALSE**, the NDK functionality of the miniport adapter must be disabled.

To enable or disable its NDK functionality, the miniport driver's *MiniportOidRequest* callback function should follow the steps in Enabling and Disabling NDK Functionality.

Note An NDK-capable miniport driver must never call **NdisMNetPnPEvent** from the context of its *MiniportOidRequest* function, because doing so could cause a deadlock. Instead, it should call **NdisMNetPnPEvent** from some other context or queue a work item.

An NDK-capable miniport driver's *MiniportOidRequest* function must return **STATUS_SUCCESS** for an OID_NDK_SET_STATE OID request unless a failure occurs. The driver must not return **NDIS_STATUS_PENDING**.

Requirements

Minimum supported client	None supported
Minimum supported server	Windows Server 2012
Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDK_ADAPTER

OID_NDK_SET_STATE

OID_NDK_STATISTICS

Article • 02/18/2023

As a query, NDIS and overlying drivers or user-mode applications use the OID_NDK_STATISTICS OID to get the NDK statistics of a miniport adapter.

NDIS 6.30 and later miniport drivers that provide NDK services must support this OID. Otherwise, this OID is optional.

Note NDIS supports this OID with the direct OID request interface. For more information about the direct OID request interface, see NDIS 6.1 Direct OID Request Interface.

Remarks

NDIS issues this OID with the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure pointing to an **NDIS_NDK_STATISTICS_INFO** structure.

The NDK-capable miniport driver must provide the **CounterSet** member, which is a **NDIS_NDK_PERFORMANCE_COUNTERS** structure.

The counters are published to tools such as perfmon (see the NetworkDirect Activity performance counter) and made available programmatically with the Performance Data Helper (PDH) and Performance Library (PERFLIB) programming interfaces. For more information about these interfaces, see Performance Counters.

These counters are also available by calling the Get-NetAdapterStatistics PowerShell cmdlet with the **RdmaStatistics** attribute. For more information about the **RdmaStatistics** attribute, see **MSFT_NetAdapterStatisticsSettingData**.

Requirements

Minimum supported client	None supported
Minimum supported server	Windows Server 2012
Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_NDK_STATISTICS_INFO

NDIS_OID_REQUEST

OID_NIC_SWITCH_ALLOCATE_VF

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_NIC_SWITCH_ALLOCATE_VF to allocate resources for a PCI Express (PCIe) Virtual Function (VF). The VF is exposed on a network adapter that supports the single root I/O virtualization (SR-IOV) interface.

Overlying drivers issue this OID method request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

Remarks

The PF miniport driver allocates software resources for a VF when the driver handles an object identifier (OID) method request of OID_NIC_SWITCH_ALLOCATE_VF. Even though the hardware resources have been allocated for a VF, it is considered to be nonoperational until the PF miniport driver successfully completes the OID_NIC_SWITCH_ALLOCATE_VF.

For more information about how to allocate VF resources, see Allocating Resources for a Virtual Function.

Note After an overlying driver requests resource allocation for a VF, that driver is the only component that can request the freeing of the resources for the same VF. The overlying driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the VF resources. Before the overlying driver can be halted, it must free the resources for each VF that was allocated by the driver's OID_NIC_SWITCH_ALLOCATE_VF request.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	**Description**
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_VF_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_VF_PARAMETERS). The PF miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_NIC_SWITCH_CREATE_SWITCH

OID_NIC_SWITCH_CREATE_VPORT

NDIS_NIC_SWITCH_VF_PARAMETERS

OID_NIC_SWITCH_FREE_VF

OID_NIC_SWITCH_CREATE_SWITCH

Article • 02/18/2023

NDIS issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH to create a NIC switch on a network adapter. When it handles this OID request, the miniport driver allocates the resources for the NIC switch on the adapter.

NDIS issues this OID method request to the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

Note Overlying drivers, such as protocol or filter drivers, cannot issue OID method requests of OID_NIC_SWITCH_CREATE_SWITCH to the PF miniport driver.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_PARAMETERS** structure.

Remarks

When it receives the OID method request of OID_NIC_SWITCH_CREATE_SWITCH, the PF miniport driver must do the following:

1. If the PF miniport driver supports static switch creation and configuration, it creates the NIC switch when NDIS calls *MiniportInitializeEx*. When the driver handles this OID request, it must verify the configuration parameters in the **NDIS_NIC_SWITCH_PARAMETERS** structure. The parameters must be the same as those used by the driver to create the switch during the call to *MiniportInitializeEx*. If this is not true, the driver must fail the OID request.

   For more information, see Static Creation of a NIC Switch.

2. If the PF miniport driver supports dynamic switch creation and configuration, the driver must validate the configuration values of the **NDIS_NIC_SWITCH_PARAMETERS** structure and create the NIC switch based on these values.

   For more information, see Dynamic Creation of a NIC Switch.

3. The PF miniport driver must allocate the necessary hardware and software resources for the default VPort on the NIC switch.

Note The default VPort is always created through an OID request of OID_NIC_SWITCH_CREATE_SWITCH and deleted through an OID request of OID_NIC_SWITCH_DELETE_SWITCH. OID requests of OID_NIC_SWITCH_CREATE_VPORT and OID_NIC_SWITCH_DELETE_VPORT are used for the creation and deletion of nondefault VPorts on the NIC switch.

4. The PF miniport driver that supports dynamic switch creation and configuration must enable SR-IOV virtualization on the switch by calling **NdisMEnableVirtualization**. This call configures the **NumVFs** member and the **VF Enable** bit in the SR-IOV Extended Capability structure of the adapter's PCI Express (PCIe) configuration space.

   For more information about the SR-IOV configuration space, see the PCI-SIG Single Root I/O Virtualization and Sharing 1.1 specification.

   Note If the PF miniport driver supports static switch creation, it enables SR-IOV virtualization after it creates the switch when *MiniportInitializeEx* is called.

If the PF miniport driver successfully completes the OID method request of OID_NIC_SWITCH_CREATE_SWITCH, it allows the following to occur:

- VFs can be allocated on the NIC switch through OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.
- Nondefault VPorts can be created on the NIC switch through OID method requests of OID_NIC_SWITCH_CREATE_VPORT.

For more information on how to handle this OID request, see Handling the OID_NIC_SWITCH_CREATE_SWITCH Request.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID method request of OID_NIC_SWITCH_CREATE_SWITCH.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the SR-IOV interface or is not enabled to use the interface.

Status Code	Description
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_PARAMETERS). The PF miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

NdisMEnableVirtualization

OID_NIC_SWITCH_ALLOCATE_VF

OID_NIC_SWITCH_CREATE_VPORT

OID_NIC_SWITCH_CREATE_VPORT

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_VPORT to create a nondefault virtual port (VPort) on a network adapter's NIC switch. This OID method request also attaches the created VPort to the network adapter's PCI Express (PCIe) Physical Function (PF) or a previously allocated PCIe Virtual Function (VF).

Overlying drivers issue this OID method request to the miniport driver for the network adapter's PF. This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure.

Remarks

The overlying driver initializes the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure with the configuration information about the nondefault VPort to be created. The configuration information includes the PCIe function to which the nondefault VPort is attached and the number of queue pairs for the nondefault VPort.

When the PF miniport driver is issued the OID request, the driver allocates the hardware and software resources associated with the specified nondefault VPort. After all the resources are successfully allocated, the PF miniport driver completes the OID successfully by returning NDIS_STATUS_SUCCESS from *MiniportOidRequest*.

If the OID_NIC_SWITCH_CREATE_VPORT request completes successfully, the PF miniport driver and the overlying driver must retain the **VPortId** value of the nondefault VPort for successive operations. The **VPortId** value is used during these operations:

- NDIS and the overlying drivers use the **VPortId** value to identify the nondefault VPort in successive OID requests related to this VPort, such as OID_NIC_SWITCH_VPORT_PARAMETERS and OID_NIC_SWITCH_DELETE_VPORT.

- During send operations, NDIS specifies the **VPortId** value to identify the VPort from which a packet was sent. This value is specified within the out-of-band (OOB) **NDIS_NET_BUFFER_LIST_FILTERING_INFO** data of the NET_BUFFER_LIST structure.

- During receive operations, the PF miniport driver specifies the **VPortId** value to which a packet is to be forwarded. This value is also specified in the OOB

NDIS_NET_BUFFER_LIST_FILTERING_INFO data of the NET_BUFFER_LIST structure.

For more information, see Creating a Virtual Port.

Note The default VPort always exists and is not created though an OID request of OID_NIC_SWITCH_CREATE_VPORT. The default VPort has an identifier of NDIS_DEFAULT_VPORT_ID. When the PF miniport driver creates a NIC switch, the driver automatically attaches the default VPort to the PF of the network adapter.

Return Status Codes

NDIS or the PF miniport driver returns one of the following status codes for the OID method request of OID_NIC_SWITCH_CREATE_SWITCH.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the SR-IOV interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_VPORT_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_VPORT_PARAMETERS). The PF miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_NIC_SWITCH_CURRENT_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_NIC_SWITCH_CURRENT_CAPABILITIES to obtain the currently enabled hardware capabilities of the NIC switch in a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_NIC_SWITCH_CAPABILITIES structure.

Remarks

Starting with NDIS 6.20, miniport drivers supply the currently enabled NIC switch hardware capabilities on the network adapter when its *MiniportInitializeEx* function is called. The driver initializes an NDIS_NIC_SWITCH_CAPABILITIES structure with the NIC switch hardware capabilities and sets the **CurrentNicSwitchCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the **NDIS_NIC_SWITCH_CAPABILITIES** structure. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

Note Starting with NDIS 6.30, miniport drivers that support the single root I/O virtualization (SR-IOV) interface must register the enabled hardware capabilities of the NIC switch. Drivers register these capabilities by calling NdisMSetMiniportAttributes.

Overlying protocol and filter drivers do not have to issue OID query requests of OID_NIC_SWITCH_CURRENT_CAPABILITIES. NDIS provides the currently enabled NIC switch hardware capabilities of a network adapter to these drivers in the following way:

- NDIS reports the currently enabled NIC switch hardware capabilities of an underlying network adapter to overlying protocol drivers in the **NicSwitchCapabilities** member of the NDIS_BIND_PARAMETERS structure during the bind operation.

- NDIS reports the currently enabled NIC switch hardware capabilities of an underlying network adapter to overlying filter drivers in the **NicSwitchCapabilities** member of the NDIS_FILTER_ATTACH_PARAMETERS structure during the attach operation.

Return Status Codes

NDIS handles the OID query request of the OID_NIC_SWITCH_CURRENT_CAPABILITIES request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_NIC_SWITCH_CURRENT_CAPABILITIES request, it returns one of the following status codes:

Status Code	Description
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** points to an NDIS_NIC_SWITCH_CAPABILITIES structure.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_CAPABILITIES). The miniport driver must set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

NDIS_OID_REQUEST

OID_NIC_SWITCH_DELETE_SWITCH

Article • 02/18/2023

NDIS issues an object identifier (OID) set request of OID_NIC_SWITCH_DELETE_SWITCH to delete a NIC switch from a network adapter.

NDIS issues this OID set request to the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). This OID set request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

Note Overlying drivers, such as protocol or filter drivers, cannot issue this OID method request to the PF miniport driver.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_DELETE_SWITCH_PARAMETERS** structure.

Remarks

An OID set request of OID_NIC_SWITCH_DELETE_SWITCH deletes a NIC switch that was previously created through an OID method request of OID_NIC_SWITCH_CREATE_SWITCH.

When it receives the OID method request of OID_NIC_SWITCH_DELETE_SWITCH, the PF miniport driver must do the following:

1. If the PF miniport driver supports static creation and configuration of NIC switches, it must free the software resources associated with the specified NIC switch. However, the driver can only free the hardware resources for the NIC switch when *MiniportHaltEx* is called.

   For more information about static NIC switch creation, see Static Creation of a NIC Switch.

2. If the PF miniport driver supports the dynamic creation and configuration of NIC switches, it must free the hardware and software resources associated with the specified NIC switch.

   For more information about dynamic NIC switch creation, see Dynamic Creation of a NIC Switch.

3. If the PF miniport driver supports the dynamic creation and all the NIC switches have been deleted, the driver must disable virtualization on the adapter by calling

NdisMEnableVirtualization. To disable virtualization, the network adapter must set the *EnableVirtualization* parameter to FALSE and the *NumVFs* parameter to zero.

NdisMEnableVirtualization clears the **NumVFs** member and the **VF Enable** bit in the SR-IOV Extended Capability structure in the PCI configuration space of the network adapter's PF.

Note If the PF miniport driver supports static creation and configuration of NIC switches, it must only call **NdisMEnableVirtualization** when *MiniportHaltEx* is called.

For more information, see Deleting a NIC Switch.

Return Status Codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the **NdisMOidRequestComplete** function, passing NDIS_STATUS_SUCCESS for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

NDIS returns one of the following status codes for this request:

Term	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the SR-IOV interface or is not enabled to use the interface.

Term	Description
NDIS_STATUS_FILE_NOT_FOUND	One or more of the members of the NDIS_NIC_SWITCH_DELETE_SWITCH_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer is too small. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_NIC_SWITCH_DELETE_VPORT

OID_NIC_SWITCH_FREE_VF

OID_NIC_SWITCH_DELETE_VPORT

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_NIC_SWITCH_DELETE_VPORT to delete a nondefault virtual port (VPort) that was previously created on a network adapter's NIC switch. The overlying driver can delete a VPort that it has previously created only by issuing an OID method request of OID_NIC_SWITCH_CREATE_VPORT.

Overlying drivers issue this OID set request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID set request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the **NDIS_NIC_SWITCH_DELETE_VPORT_PARAMETERS** structure.

Remarks

An overlying driver, such as a protocol or filter driver, can only delete a nondefault VPort that it has previously created. The overlying driver creates a VPort by issuing an OID method request of OID_NIC_SWITCH_CREATE_VPORT.

When the PF miniport driver receives the OID request of OID_NIC_SWITCH_DELETE_VPORT, the driver must free the hardware and software resources that were allocated for the specified VPort.

For more information, see Deleting a Virtual Port.

Note Only nondefault VPorts can be explicitly deleted through OID requests of OID_NIC_SWITCH_DELETE_VPORT. The default VPort is implicitly deleted when the PF miniport driver deletes the default NIC switch. For more information, see Deleting a NIC Switch.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID set request of OID_NIC_SWITCH_DELETE_VPORT.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	Description
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_DELETE_VPORT_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_DELETE_VPORT_PARAMETERS). The PF miniport driver must set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_NIC_SWITCH_DELETE_SWITCH

OID_NIC_SWITCH_ENUM_SWITCHES

Article • 02/18/2023

An overlying driver or user-mode application issues an object identifier (OID) query request of OID_NIC_SWITCH_ENUM_SWITCHES to obtain an array. Each element in the array specifies the attributes of a NIC switch that has been created on a network adapter.

After a successful return from this OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer that contains the following:

- An NDIS_NIC_SWITCH_INFO_ARRAY structure that defines the number of elements within the array.

- An array of NDIS_NIC_SWITCH_INFO structures. Each of these structures contains the information about a single NIC switch created on the network adapter.

  Note If the network adapter has no NIC switches, the driver sets the **NumElements** member of the NDIS_NIC_SWITCH_INFO_ARRAY structure to zero and no NDIS_NIC_SWITCH_INFO structures are returned.

Remarks

Overlying drivers and user-mode applications issue OID query requests of OID_NIC_SWITCH_ENUM_SWITCHES to enumerate the NIC switches created on a network adapter.

Note Starting with Windows Server 2012, the single root I/O virtualization (SR-IOV) interface only supports the default NIC switch on the network adapter. Therefore, the returned NDIS_NIC_SWITCH_INFO_ARRAY structure must specify a single NDIS_NIC_SWITCH_INFO element for the default NIC switch, which is referenced by the identifier of NDIS_DEFAULT_SWITCH_ID.

Return Status Codes

NDIS handles the OID query request of the OID_NIC_SWITCH_ENUM_SWITCHES request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_NIC_SWITCH_ENUM_SWITCHES request, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the SR-IOV interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_INFO_ARRAY structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

OID_NIC_SWITCH_CREATE_SWITCH

OID_NIC_SWITCH_PARAMETERS

OID_NIC_SWITCH_ENUM_VFS

Article • 02/18/2023

An overlying driver or user-mode application issues an object identifier (OID) method request of OID_NIC_SWITCH_ENUM_VFS to obtain an array. Each element in the array specifies the attributes of a PCI Express (PCIe) Virtual Function (VF) that are attached to a NIC switch on a network adapter's NIC switch.

After a successful return from this OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer that contains the following:

- An **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure that defines the number of elements within the array.

- An array of **NDIS_NIC_SWITCH_VF_INFO** structures. Each of these structures contains information about a single VF on a NIC switch of the network adapter. A VF is attached to a NIC switch through OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.

  Note If no VFs are attached to a NIC switch on the network adapter, the **NumElements** member of the **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure is set to zero and no **NDIS_NIC_SWITCH_VF_INFO** structures are returned.

Remarks

Overlying drivers and user-mode applications issue OID method requests of OID_NIC_SWITCH_ENUM_VFS to enumerate the VFs attached to a network adapter's NIC switch.

Before the driver or application issues the OID request, it must initialize an **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure that is passed along with the request. The driver or application must follow these guidelines when initializing the **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure:

- If the NDIS_NIC_SWITCH_VF_INFO_ARRAY_ENUM_ON_SPECIFIC_SWITCH flag is set in the **Flags** member, the driver or application must set the **SwitchId** member to the NIC switch identifier on the SR-IOV network adapter. By setting these members in this way, VF information is returned only for the specified NIC switch on the SR-IOV network adapter.

Note The overlying driver and user-mode application can obtain the NIC switch identifiers by issuing an OID query request of OID_NIC_SWITCH_ENUM_SWITCHES.

- If the **Flags** member is set to zero, the driver or application must set the **SwitchId** member to zero. By setting these members in this way, VF information is returned for all NIC switch on the SR-IOV network adapter.

Note Starting with Windows Server 2012, Windows supports only the default NIC switch on the network adapter. Regardless of the flags set in the **Flags** member, the **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

For more information about NIC switches, see NIC Switches.

Return Status Codes

NDIS handles the OID method request of the OID_NIC_SWITCH_ENUM_VFS request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_NIC_SWITCH_ENUM_VFS request, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_NIC_SWITCH_ALLOCATE_VF

OID_NIC_SWITCH_CREATE_SWITCH

OID_NIC_SWITCH_VF_PARAMETERS

OID_NIC_SWITCH_ENUM_VPORTS

Article • 02/18/2023

An overlying driver or user-mode application issues an object identifier (OID) method request of OID_NIC_SWITCH_ENUM_VPORTS to obtain an array. Each element in the array specifies the attributes of a virtual port (VPort) that has been created on a network adapter's NIC switch.

After a successful return from this OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer that contains the following:

- An NDIS_NIC_SWITCH_VPORT_INFO_ARRAY structure that defines the number of elements within the array.

- An array of NDIS_NIC_SWITCH_VPORT_INFO structures. Each of these structures contains information about a VPort on the network adapter's NIC switch.

  Note If no VPorts have been created on the network adapter, the driver sets the **NumElements** member of the NDIS_NIC_SWITCH_VPORT_INFO_ARRAY structure to zero and no NDIS_NIC_SWITCH_VPORT_INFO structures are returned.

Remarks

Overlying drivers and user-mode applications issue OID query requests of OID_NIC_SWITCH_ENUM_VPORTS to enumerate the VPorts that are allocated on a network adapter's NIC switch.

Before the driver or application issues the OID request, it must initialize an NDIS_NIC_SWITCH_VPORT_INFO_ARRAY structure that is passed along with the request. The driver or application must follow these guidelines when initializing the **NDIS_NIC_SWITCH_VPORT_INFO_ARRAY** structure:

- If the NDIS_NIC_SWITCH_VPORT_INFO_ARRAY_ENUM_ON_SPECIFIC_SWITCH flag is set in the **Flags** member, information is returned for all VPorts created on a specified NIC switch. The NIC switch is specified by the **SwitchId** member of that structure.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only the default NIC switch on the network adapter. Regardless of the flags that are set in the **Flags** member, the **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

- If the NDIS_NIC_SWITCH_VPORT_INFO_ARRAY_ENUM_ON_SPECIFIC_FUNCTION flag is set in the **Flags** member, information is returned for all VPorts attached to a specified PCI Express (PCIe) Physical Function (PF) or Virtual Function (VF) on the network adapter. The PF or VF is specified by the **AttachedFunctionId** member of that structure.

  If the **AttachedFunctionId** member is set to NDIS_PF_FUNCTION_ID, information is returned for all VPorts, including the default VPort, that are attached to the network adapter's PF. If the **AttachedFunctionId** member is set to a valid VF identifier, information is returned for all VPorts to the specified VF.

  Note Starting with Windows Server 2012, only one nondefault VPort can be attached to a VF. However, multiple VPorts (including the default VPort) can be attached to the PF.

- If the **Flags** member is set to zero, information is returned for all VPorts attached to the PF or VF on the network adapter. In this case, the values of the **SwitchId** and **AttachedFunctionId** are ignored.

For more information, see Enumerating Virtual Ports on a Network Adapter.

Return Status Codes

NDIS handles the OID method request of the OID_NIC_SWITCH_ENUM_VPORTS request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_NIC_SWITCH_ENUM_VPORTS request, it returns one of the following status codes:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_VF_INFO_ARRAY structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Status Code	Description
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_NIC_SWITCH_FREE_VF to free the resources for a network adapter's PCI Express (PCIe) Virtual Function (VF).

Overlying drivers issue this OID set request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID set request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_FREE_VF_PARAMETERS** structure.

The overlying driver specifies the identifier of the VF to be freed through the **VFId** member of this structure. The driver obtained this identifier from an earlier OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

Remarks

An overlying driver issues an OID set request of OID_NIC_SWITCH_FREE_VF to free the resources for a VF. These resources were previously allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

For more information about how to free VF resources, see Freeing Resources for a Virtual Function.

Note Once an overlying driver requests resource allocation for a VF, that driver is the only component that can request the freeing of the resources for the same VF. The overlying driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the VF resources. Before the overlying driver can be halted, it must free the resources for each VF that was allocated by the driver's OID_NIC_SWITCH_ALLOCATE_VF request.

Return status codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.

Term	Description
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the NdisMOidRequestComplete function, passing **NDIS_STATUS_SUCCESS** for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

NDIS returns one of the following status codes for this request:

Term	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the SR-IOV interface or is not enabled to use the interface.
NDIS_STATUS_FILE_NOT_FOUND	One or more of the members of the NDIS_NIC_SWITCH_FREE_VF_PARAMETERS structure have invalid values. For example, the **VFId** member might specify a VF that either has not been allocated or that has VPorts that have not been deleted.
NDIS_STATUS_INVALID_LENGTH	The information buffer is too small. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_NIC_SWITCH_DELETE_SWITCH

OID_NIC_SWITCH_HARDWARE_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_NIC_SWITCH_HARDWARE_CAPABILITIES to obtain the hardware capabilities of the NIC switch in the network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_NIC_SWITCH_CAPABILITIES structure.

Remarks

The NDIS_NIC_SWITCH_CAPABILITIES structure contains information about the hardware capabilities of a NIC switch on the network adapter. These capabilities can include the hardware capabilities that are currently disabled by the INF file settings or through the **Advanced** properties page.

Note All the capabilities of the specified NIC switch are returned through an OID query request of OID_NIC_SWITCH_HARDWARE_CAPABILITIES, regardless of whether a capability is enabled or disabled.

Starting with NDIS 6.20, miniport drivers supply the NIC switch hardware capabilities when its *MiniportInitializeEx* function is called. The driver initializes an NDIS_NIC_SWITCH_CAPABILITIES structure with the NIC switch hardware capabilities and sets the **HardwareNicSwitchCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the **NDIS_NIC_SWITCH_CAPABILITIES** structure. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

Note Starting with NDIS 6.30, miniport drivers that support the single root I/O virtualization (SR-IOV) interface must register the hardware capabilities of the NIC switch. Drivers register these capabilities by calling NdisMSetMiniportAttributes.

Return Status Codes

NDIS handles the OID query request of OID_NIC_SWITCH_HARDWARE_CAPABILITIES request for miniport drivers, and returns one of the following status codes:

Status Code	Description
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** points to an NDIS_NIC_SWITCH_CAPABILITIES structure.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_CAPABILITIES). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

NDIS_OID_REQUEST

OID_NIC_SWITCH_PARAMETERS

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_NIC_SWITCH_PARAMETERS to obtain the current configuration parameters of a specified NIC switch on a network adapter. NDIS handles these OID method requests for the miniport driver.

Overlying drivers issue an OID set request of OID_NIC_SWITCH_PARAMETERS to set the configuration parameters of a specified NIC switch on a network adapter. These OID set requests are issued to the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). These OID set requests are required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_PARAMETERS** structure.

The overlying driver specifies the NIC switch for the OID method or set request by setting the **SwitchId** member of the **NDIS_NIC_SWITCH_PARAMETERS** structure to the switch identifier. The overlying driver obtains the switch identifier through one of the following ways:

- From a previous OID method request of OID_NIC_SWITCH_ENUM_SWITCHES.
- From the **NicSwitchArray** member of the **NDIS_BIND_PARAMETERS** structure. NDIS passes a pointer to this structure in the *BindParameters* parameter of the *ProtocolBindAdapterEx* function.
- From the **NicSwitchArray** member of the **NDIS_FILTER_ATTACH_PARAMETERS** structure. NDIS passes a pointer to this structure in the *AttachParameters* parameter of the *FilterAttach* function.

Note Starting with Windows Server 2012, Windows supports only the default NIC switch on the network adapter. The **SwitchId** member of the **NDIS_NIC_SWITCH_PARAMETERS** structure must be set to NDIS_DEFAULT_SWITCH_ID.

Remarks

The overlying driver issues OID_NIC_SWITCH_PARAMETERS requests in the following way:

- The overlying driver issues an OID method request of OID_NIC_SWITCH_PARAMETERS to obtain the current parameters of a specified NIC switch. For more information, see Querying the Parameters of a NIC Switch.

  Note NDIS handles OID method requests of OID_NIC_SWITCH_PARAMETERS for the PF miniport driver.

- The overlying driver issues an OID set request of OID_NIC_SWITCH_PARAMETERS to change the current parameters of a specified NIC switch. For more information, see Setting the Parameters of a NIC Switch.

  Note The PF miniport driver handles OID set requests of OID_NIC_SWITCH_PARAMETERS.

Return Status Codes

NDIS or the PF miniport driver returns the following status codes for set or method OID requests of OID_NIC_SWITCH_PARAMETERS.

Status Code	**Description**
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** points to an NDIS_NIC_SWITCH_CAPABILITIES structure.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS or the PF miniport driver sets the **DATA.METHOD_INFORMATION.BytesNeeded** member (for OID method requests) or **DATA.SET_INFORMATION.BytesNeeded** member (for OID set requests) in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_REINIT_REQUIRED	The PF miniport driver requires a reinitialization of the network adapter to apply the changes to the NIC switch.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_NIC_SWITCH_VF_PARAMETERS

Article • 02/18/2023

An overlying driver or user-mode application issues an object identifier (OID) method request of OID_NIC_SWITCH_VF_PARAMETERS to obtain the current configuration parameters of a PCI Express (PCIe) Virtual Function (VF) on a network adapter. Only VFs that have resources allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF can be queried through an OID method request of OID_NIC_SWITCH_VF_PARAMETERS.

NDIS handles the OID method request of OID_NIC_SWITCH_VF_PARAMETERS for miniport drivers.

When the OID method request is made, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

Remarks

The overlying driver or user-mode application specifies the VF to query by setting the **VFId** member of the **NDIS_NIC_SWITCH_VF_PARAMETERS** structure to the identifier of the VF. The overlying driver or application obtains the VF identifier through one of the following ways:

- By issuing an OID method request of OID_NIC_SWITCH_ENUM_VFS.

  If this OID request is completed successfully, the overlying driver or user-mode application receives a list of all VFs allocated on the network adapter. Each element within the list is an **NDIS_NIC_SWITCH_VF_INFO** structure, with the VF identifier specified by the **VFId** member.

- By issuing an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

  If this OID request is completed successfully, the overlying driver receives the identifier of the newly created VF in the **VFId** member of the returned **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

  Note Only overlying drivers can obtain the VF identifier in this manner.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an

NDIS_NIC_SWITCH_VF_PARAMETERS structure. This structure contains the configuration parameters for the specified VF.

Return Status Codes

NDIS handles the OID method request of OID_NIC_SWITCH_VF_PARAMETERS for miniport drivers, and returns the following status code for OID method requests of OID_NIC_SWITCH_VF_PARAMETERS.

Status Code	Description
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** member points to an NDIS_NIC_SWITCH_VF_PARAMETERS structure.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_VF_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_NIC_SWITCH_VF_PARAMETERS). NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_NIC_SWITCH_VPORT_PARAMETERS

Article • 02/18/2023

An overlying driver can obtain the parameters for a virtual port (VPort) on a NIC switch that has been created on a network adapter that supports single root I/O virtualization (SR-IOV). The driver issues an object identifier (OID) method request of OID_NIC_SWITCH_VPORT_PARAMETERS to obtain these parameters.

Overlying drivers issue an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS to set the configuration parameters of a specified VPort that is attached to the network adapter's NIC switch. These OID set requests are issued to the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). These OID set requests are required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure.

The overlying driver specifies the VPort for the OID method or set request by setting the **VPortId** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

- From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.
- From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

Remarks

OID_NIC_SWITCH_VPORT_PARAMETERS can be used in either OID method requests or OID set requests.

Handling OID Method Requests of OID_NIC_SWITCH_VPORT_PARAMETERS

Overlying drivers issue an OID method request of OID_NIC_SWITCH_VPORT_PARAMETERS to query the current configuration parameters of a VPort that is attached to the network adapter's NIC switch. Overlying drivers specify the VPort to query by setting the **VPortId** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure to the VPort identifier.

NDIS handles the OID method request of OID_NIC_SWITCH_VPORT_PARAMETERS for miniport drivers. NDIS returns information that it obtained from previous OID requests of OID_NIC_SWITCH_CREATE_VPORT and OID_NIC_SWITCH_ENUM_VPORTS.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure. This structure contains the configuration parameters for the specified switch.

For more information, see Querying the Parameters of a Virtual Port.

Handling OID Set Requests of OID_NIC_SWITCH_VPORT_PARAMETERS

Overlying drivers issue an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS to change the current configuration parameters of a VPort that is attached to a network adapter's NIC switch. This OID request can be used to update the parameters for default as well as nondefault VPorts.

Only a limited subset of configuration parameters for a VPort can be changed. The overlying driver specifies the parameter to change by setting the following members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure:

1. The **VPortId** member is set to the identifier of the VPort whose parameters will be changed.

2. The appropriate NDIS_NIC_SWITCH_VPORT_PARAMETERS_*Xxx*_CHANGED flags are set in the **Flags** member. Members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure can only be changed if a corresponding NDIS_NIC_SWITCH_PARAMETERS_*Xxx*_CHANGED flag is defined in Ntddndis.h.

3. The corresponding members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure are set with the VPort configuration parameters that are to be changed.

After the PF miniport driver receives the OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS, the driver configures the hardware with the configuration parameters. The driver can only change those configuration parameters identified by NDIS_NIC_SWITCH_VPORT_PARAMETERS_*Xxx*_CHANGED flags in the **Flags** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure.

For more information, see Setting the Parameters of a Virtual Port.

Return Status Codes

NDIS or the PF miniport driver returns the following status code for set or method OID requests of OID_NIC_SWITCH_VPORT_PARAMETERS.

Status Code	Description
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** points to an NDIS_NIC_SWITCH_CAPABILITIES structure.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_NIC_SWITCH_VPORT_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS or the PF miniport driver sets the **DATA.METHOD_INFORMATION.BytesNeeded** member (for OID method requests) or **DATA.SET_INFORMATION.BytesNeeded** member (for OID set requests) in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_NIC_SWITCH_CREATE_VPORT

OID_NIC_SWITCH_ENUM_VPORTS

OID_OFFLOAD_ENCAPSULATION

Article • 02/18/2023

As a query request, overlying drivers use the OID_OFFLOAD_ENCAPSULATION OID to obtain the current task offload encapsulation settings of an underlying miniport adapter. NDIS handles this OID query for miniport drivers.

As a set request, overlying drivers use the OID_OFFLOAD_ENCAPSULATION OID to set the task offload encapsulation settings of an underlying miniport adapter. Miniport drivers that support task offload must handle this OID set request.

Remarks

The InformationBuffer member of the NDIS_OID_REQUEST structure contains an NDIS_OFFLOAD_ENCAPSULATION structure.

Miniport drivers

If a miniport driver does not support offload and this OID, the driver should return NDIS_STATUS_NOT_SUPPORTED.

Miniport drivers must use the contents of the NDIS_OFFLOAD_ENCAPSULATION structure to update the currently reported TCP offload capabilities. After the update, the miniport driver must report the current task offload capabilities with the NDIS_STATUS_TASK_OFFLOAD_CURRENT_CONFIG status indication. This status indication ensures that all of the overlying protocol drivers are updated with the new capabilities information.

This OID is used to activate all configured or enabled offloads, or deactivate all offloads (in other words, the hardware starts to perform the offloads). It does not provide fine control over individual offloads. Instead, OID_TCP_OFFLOAD_PARAMETERS is used to configure individual offloads and can also activate them. Generally, most TCP/IP task offloads can be configured and activated with OID_TCP_OFFLOAD_PARAMETERS.

However, this OID's NDIS_OFFLOAD_ENCAPSULATION structure also covers two other encapsulation types that are not covered by OID_TCP_OFFLOAD_PARAMETERS's NDIS_OFFLOAD_PARAMETERS structure: **NDIS_ENCAPSULATION_IEEE_802_3** and **NDIS_ENCAPSULATION_IEEE_LLC_SNAP_ROUTED**. Miniport drivers need to handle this difference in encapsulation types that are covered by the different OIDs.

If this OID is issued by the protocol driver to deactivate all offloads, the **Enabled** member of the NDIS_OFFLOAD_ENCAPSULATION member will be set to NDIS_OFFLOAD_SET_OFF.

Setting encapsulation (protocol drivers)

Protocol drivers set OID_OFFLOAD_ENCAPSULATION after determining the system encapsulation requirements. A protocol driver can determine the capabilities of the underlying miniport adapter from the NDIS_BIND_PARAMETERS structure or by querying OID_TCP_OFFLOAD_CURRENT_CONFIG. The protocol driver must set an encapsulation type that the miniport adapter supports on at least one offload service.

If a miniport driver supports any offload type that supports the requested encapsulation type, the driver must return NDIS_STATUS_SUCCESS in response to a set of OID_OFFLOAD_ENCAPSULATION. Otherwise, the miniport driver should return NDIS_STATUS_INVALID_PARAMETER.

For send operations, a protocol driver can issue send requests by using only those offload types that the miniport adapter supports with the required encapsulation type. Therefore, if an OID set request of OID_OFFLOAD_ENCAPSULATION fails, the protocol driver must not use any offload settings in send requests that are directed to that miniport adapter.

For receive operations, the miniport driver must not start checksum or Internet protocol security (IPsec) offload services until after it receives an OID set request of OID_OFFLOAD_ENCAPSULATION.

Obtaining current encapsulation settings (protocol drivers)

A protocol driver can issue an OID_OFFLOAD_ENCAPSULATION query only after setting the OID_OFFLOAD_ENCAPSULATION OID.

NDIS responds with an NDIS_OFFLOAD_ENCAPSULATION structure that contains the current encapsulation settings.

Protocol drivers must be prepared to handle any NDIS_STATUS_Xxx failure code. If a failure occurs, the protocol driver must not attempt to perform any offload operations that are directed to the affected miniport adapter.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_PACKET_COALESCING_FILTER_MATCH_COUNT

Article • 02/18/2023

NDIS issues an OID query request of OID_PACKET_COALESCING_FILTER_MATCH_COUNT to obtain the number of packets that were cached, or *coalesced*, on the network adapter. The network adapter coalesces received packets if the adapter is enabled for NDIS packet coalescing and the packet matches a receive filter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a caller-allocated ULONG64 variable. Before a successful return from the query request, the driver updates the ULONG64 variable with the number of packets that have matched receive filters on the network adapter.

Remarks

Starting with NDIS 6.30, drivers that support NDIS packet coalescing must support OID query requests of OID_PACKET_COALESCING_FILTER_MATCH_COUNT.

Note Drivers that support the single root I/O virtualization (SR-IOV) or virtual machine queue (VMQ) interfaces are not required to support OID query requests of this OID.

A miniport driver that supports packet coalescing must increment a ULONG64 counter for each received packet that was coalesced on the network adapter. Packets are coalesced if they match a receive filter, which overlying drivers download to the miniport driver through OID method requests of OID_RECEIVE_FILTER_SET_FILTER.

The driver returns the value of this counter when it handles an OID query request of OID_PACKET_COALESCING_FILTER_MATCH_COUNT.

The miniport driver must not clear the counter after it handles the OID query request of OID_PACKET_COALESCING_FILTER_MATCH_COUNT. The miniport driver must only clear the counter if the following conditions are true:

- The miniport driver handles an OID set request of OID_PNP_SET_POWER to resume to a full-power state of NdisDeviceStateD0.
- NDIS calls the miniport driver's *MiniportResetEx* function to reset the underlying network adapter.

For more information about packet coalescing, see NDIS Packet Coalescing.

Return status codes

The miniport driver returns one of the following status codes for the OID method request of OID_PACKET_COALESCING_FILTER_MATCH_COUNT:

NDIS_STATUS_SUCCESS
The OID request completed successfully.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. The driver sets the **DATA.SET_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for other reasons.

OID_PNP_SET_POWER

OID_RECEIVE_FILTER_SET_FILTER

OID_PD_CLOSE_PROVIDER

Article • 02/18/2023

An NDIS protocol or filter driver sends an object identifier (OID) method request of OID_PD_CLOSE_PROVIDER to the PDPI provider to give up access to the PD capability in a PDPI provider object.

An NDIS protocol or filter driver must call this OID when it receives an unbind notification, a pause indication, a low-power event, or a PD configuration change event that indicates the PD is disabled on the binding.

Before calling this OID, the NDIS protocol or filter driver must ensure that it has closed and freed all PD objects such as queues, counters, and filters that it created over the PD provider instance. The NDIS protocol or filter driver must guarantee that there are no in-progress calls to any of the PD provider dispatch table functions before issuing this OID.

MiniportOidRequest

NDIS_PD_CONFIG

NDIS_OID_REQUEST

OID_PM_ADD_PROTOCOL_OFFLOAD

Article • 02/18/2023

As a set, NDIS protocol drivers use the OID_PM_ADD_PROTOCOL_OFFLOAD OID to add a protocol offload for power management to a network adapter. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_PM_PROTOCOL_OFFLOAD** structure.

Remarks

NDIS 6.20 and later protocol drivers use OID_PM_ADD_PROTOCOL_OFFLOAD OID to add a protocol offload for power management to a network adapter. If the request is successful, the network adapter must generate and transmit the necessary response packets for the offloaded protocol when the network adapter is in a low power state.

A protocol driver can offload a protocol after it successfully binds to an underlying network adapter and as soon as it has the necessary data (such as the IP address of the interface) to offload the protocol. The protocol driver can also offload a protocol in response to some other power management event notifications, such as the rejection of a previously added WOL pattern or an offloaded protocol.

To avoid race conditions in NDIS and other protocol drivers that are bound to the same miniport adapter, after NDIS starts to set a network adapter to a low power state, it will fail any attempt to offload another protocol to that network adapter. For example, if an NDIS protocol driver tries to offload a protocol in the context of processing a **NetEventSetPower** event notification for that network adapter, NDIS will fail the request.

Before NDIS sends this OID request down to the underlying NDIS drivers or completes the request to the overlying driver, it sets the ULONG **ProtocolOffloadId** member of the **NDIS_PM_PROTOCOL_OFFLOAD** structure to a unique value. Protocol drivers and NDIS use this protocol offload identifier with the OID_PM_REMOVE_PROTOCOL_OFFLOAD OID request to remove the protocol offload from the underlying network adapter.

Note The protocol offload identifier is a unique value for each of the protocol offloads that are set on a network adapter. However, the protocol offload identifier is not globally unique across all network adapters.

If NDIS or an underlying network adapter rejects an offload, it generates an **NDIS_STATUS_PM_OFFLOAD_REJECTED** status indication. This can occur after returning NDIS_STATUS_SUCCESS for the OID. The **StatusBuffer** member of the

NDIS_STATUS_INDICATION structure contains the ULONG protocol offload identifier of the rejected protocol offload.

For information on how a Native 802.11 Wireless LAN miniport driver uses this OID, see Adding and Deleting Low Power Protocol Offloads.

The miniport driver returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The requested protocol offload was added successfully. The **ProtocolOffloadId** member of the NDIS_PM_PROTOCOL_OFFLOAD structure contains a protocol offload identifier.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_PM_PROTOCOL_OFFLOAD_LIST_FULL
The request failed because the protocol offload list is full and the network adapter cannot add another protocol offload.

NDIS_STATUS_RESOURCES
NDIS or an underlying network adapter could not add the new protocol offload due to lack of resources.

NDIS_STATUS_INVALID_PARAMETER
One or more parameters in the NDIS_PM_PROTOCOL_OFFLOAD structure were invalid.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED
The network adapter does not support the requested protocol offload.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Mandatory for miniport drivers.
Header	Ntddndis.h (include Ndis.h)

Adding and Deleting Low Power Protocol Offloads

OID_PM_ADD_WOL_PATTERN

Article • 02/18/2023

As a set, NDIS protocol drivers use the OID_PM_ADD_WOL_PATTERN OID to add a power management wake-on-LAN pattern to a network adapter. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_PM_WOL_PATTERN** structure.

Remarks

NDIS 6.20 and later protocol drivers use OID_PM_ADD_WOL_PATTERN to add a Wake on LAN (WOL) pattern to a network adapter. The OID request contains criterion that the network adapter must compare to incoming packets when it is in a low power state. The network adapter must generate a wake up event when it receives a packet that matches the pattern criteria.

A protocol driver can add WOL patterns after it successfully binds to an underlying network adapter and as soon as it has the necessary data (such as the IP address of the interface) to set up the WOL pattern. The protocol driver can also add a WOL pattern in response to some other power management event notifications such as the rejection of a previously added WOL pattern or an offloaded protocol.

To avoid race conditions in NDIS and other protocol drivers that are bound to the same miniport adapter, after NDIS starts to set a network adapter to a low power state, it will fail any attempt to add a new wake up pattern to that network adapter. For example, if an NDIS protocol driver tries to add a new WOL pattern in the context of processing a **NetEventSetPower** event notification for that network adapter, NDIS will fail the request.

Before NDIS sends this OID request down to the underlying NDIS drivers or completes the request to the overlying driver, it sets the ULONG **PatternId** member of the **NDIS_PM_WOL_PATTERN** structure to a unique value. Protocol drivers and NDIS use this pattern identifier with the OID_PM_REMOVE_WOL_PATTERN OID request to remove the WOL pattern from the underlying network adapter.

Note The pattern identifier is a unique value for each of the patterns that are set on a network adapter. However, the pattern identifier is not globally unique across all miniport adapters.

If NDIS or an underlying network adapter removes a WOL pattern, it generates an **NDIS_STATUS_PM_WOL_PATTERN_REJECTED** status indication. The **StatusBuffer** member of the NDIS_STATUS_INDICATION structure contains the ULONG WOL pattern identifier of the rejected WOL pattern.

The miniport driver returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The requested pattern was added successfully. The **PatternId** member of the NDIS_PM_WOL_PATTERN structure contains a pattern identifier.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_PM_WOL_PATTERN_LIST_FULL
The request failed because the pattern list is full and the network adapter cannot add another pattern.

NDIS_STATUS_RESOURCES
NDIS or underlying network adapter could not add the new pattern due to lack of resources.

NDIS_STATUS_INVALID_PARAMETER
One or more parameters in the NDIS_PM_WOL_PATTERN structure were invalid.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED
The network adapter does not support the requested WOL pattern.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Mandatory for miniport drivers.
Header	Ntddndis.h (include Ndis.h)

OID_PM_CURRENT_CAPABILITIES

Article • 02/18/2023

As a query, overlying drivers can use the OID_PM_CURRENT_CAPABILITIES OID to query the currently available power management capabilities of a network adapter. After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_PM_CAPABILITIES structure.

Remarks

NDIS handles the query for miniport drivers. Starting with NDIS 6.20, miniport drivers supply the power management hardware capabilities during initialization. However, NDIS can hide some capabilities from the protocol driver. For example, NDIS might report different capabilities when a user disables some or all of the power management capabilities.

Note that the current power management capabilities that NDIS reports to a protocol driver are not necessarily the same as the hardware capabilities that the miniport driver reported to NDIS.

NDIS reports the power management capabilities of an underlying network adapter to overlying protocol drivers in the **PowerManagementCapabilitiesEx** member of the NDIS_BIND_PARAMETERS structure during the bind operation. Therefore, protocol drivers do not have to query the OID.

NDIS issues an NDIS_STATUS_PM_CAPABILITIES_CHANGE status indication to report changes in the power management capabilities that are available to overlying drivers.

If the underlying network adapter has an NDIS 6.1 or older miniport driver, NDIS translates the power management capabilities of the underlying network adapter to an NDIS_PM_CAPABILITIES structure.

NDIS returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an NDIS_PM_CAPABILITIES structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Not requested for miniport drivers. (See Remarks section.)

OID_PM_GET_PROTOCOL_OFFLOAD

Article • 02/18/2023

An overlying driver issues an OID method request of OID_PM_GET_PROTOCOL_OFFLOAD to obtain parameter settings for a low power protocol offload from a network adapter.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure initially contains a pointer to a ULONG protocol offload identifier. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an NDIS_PM_PROTOCOL_OFFLOAD structure.

Remarks

NDIS 6.20 and later protocol drivers use OID_PM_GET_PROTOCOL_OFFLOAD method OID to retrieve parameter settings for a low power protocol offload from a network adapter.

The information buffer must point to a ULONG-type protocol offload identifier. NDIS set this protocol offload identifier in the **ProtocolOffloadId** member of the NDIS_PM_PROTOCOL_OFFLOAD structure when NDIS sent the prior OID_PM_ADD_PROTOCOL_OFFLOAD OID request to the underlying network adapter.

The miniport driver returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The requested data was retrieved successfully. The information buffer contains the corresponding NDIS_PM_PROTOCOL_OFFLOAD structure.

NDIS_STATUS_PENDING
The request is pending completion. The final status code and results will be passed to the OID request completion handler of the caller.

NDIS_STATUS_INVALID_PARAMETER
The specified protocol offload identifier was not valid.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED

The NDIS version of the miniport driver is below 6.20.

NDIS_STATUS_FAILURE

The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Mandatory for miniport drivers. (See Remarks section.)
Header	Ntddndis.h (include Ndis.h)

OID_PM_HARDWARE_CAPABILITIES

Article • 02/18/2023

As a query, overlying drivers can use the OID_PM_HARDWARE_CAPABILITIES OID to query the power management hardware capabilities of a network adapter. After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_PM_CAPABILITIES structure.

Remarks

NDIS handles the query for miniport drivers. Starting with NDIS 6.20, miniport drivers supply the power management hardware capabilities during initialization in the **PowerManagementCapabilitiesEx** member of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure.

The miniport driver must issue an NDIS_STATUS_PM_CAPABILITIES_CHANGE status indication to report changes in the power management hardware capabilities of a network adapter to NDIS and overlying drivers.

NDIS returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an NDIS_PM_CAPABILITIES structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Not

	requested for miniport drivers. (See Remarks section.)

OID_PM_PARAMETERS

Article • 02/18/2023

As a query, protocol drivers can use the OID_PM_PARAMETERS OID to query the power management hardware capabilities of a network adapter that are currently enabled. After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_PM_PARAMETERS structure.

As a set, protocol drivers can use the OID_PM_PARAMETERS OID to enable or disable the current hardware capabilities of a network adapter. The protocol driver provides a pointer to an NDIS_PM_PARAMETERS structure in the **InformationBuffer** member of the NDIS_OID_REQUEST structure.

Remarks

Starting with NDIS 6.20, overlying protocol and filter drivers use OID_PM_PARAMETERS to query and set the power management hardware capabilities of a network adapter that are currently enabled.

When an overlying driver queries the OID_PM_PARAMETERS OID, NDIS completes the request without forwarding it to the miniport driver. NDIS stores the requested settings and combines them with the settings from other such requests. Before NDIS transitions the network adapter to the low power state, NDIS sends a set request to the miniport driver that contains the combined settings from all of the requests that NDIS stored.

The capabilities that are currently enabled can be a subset of the capabilities that the hardware supports. For more information about the capabilities that the hardware supports, see OID_PM_HARDWARE_CAPABILITIES.

Note If NDIS sets the NDIS_PM_SELECTIVE_SUSPEND_ENABLED flag in the **WakeUpFlags** member of NDIS_PM_PARAMETERS structure, it issues the OID set request of OID_PM_PARAMETERS directly to the miniport driver. This allows NDIS to bypass the processing by filter drivers in the networking driver stack.

NDIS or the miniport driver returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The request completed successfully.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to

the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_INVALID_PARAMETER
The request failed because it tried to enable a capability that the underlying network adapter does not support.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_PM_PARAMETERS

OID_PM_HARDWARE_CAPABILITIES

OID_PM_PROTOCOL_OFFLOAD_LIST

Article • 02/18/2023

As a query, overlying drivers can use the OID_PM_PROTOCOL_OFFLOAD_LIST OID to enumerate the protocol offloads that are set on an underlying network adapter. After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a list of NDIS_PM_PROTOCOL_OFFLOAD structures that describe the currently active protocol offloads.

Remarks

NDIS handles the query for miniport drivers. NDIS drivers can use the OID_PM_PROTOCOL_OFFLOAD_LIST OID to get a list of protocol offloads that are set on an underlying network adapter.

For each NDIS_PM_PROTOCOL_OFFLOAD structure in the list, NDIS sets the **NextProtocolOffloadOffset** member to the offset from the beginning of the OID information buffer (that is, the beginning of the buffer that the **InformationBuffer** member of the NDIS_OID_REQUEST structure points to) to the beginning of the next NDIS_PM_PROTOCOL_OFFLOAD structure in the list. The offset in the **NextProtocolOffloadOffset** member of the last structure in the list is zero.

If there are no protocol offloads that are set on the network adapter, NDIS sets the **DATA.QUERY_INFORMATION.BytesWritten** member of the NDIS_OID_REQUEST structure to zero and returns NDIS_STATUS_SUCCESS. The data within the **DATA.QUERY_INFORMATION.InformationBuffer** member is not modified by NDIS.

NDIS returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** contains a pointer to a list of protocol offloads, if any.

NDIS_STATUS_PENDING
The request is pending completion. The final status code and results will be passed to the OID request completion handler of the caller.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the

DATA.QUERY_INFORMATION.BytesNeeded member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Not requested for miniport drivers. (See Remarks section.)
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_PM_PROTOCOL_OFFLOAD

OID_PM_REMOVE_PROTOCOL_OFFLOAD

Article • 02/18/2023

As a set request, NDIS and protocol drivers use the OID_PM_REMOVE_PROTOCOL_OFFLOAD OID to remove a power management protocol offload from a network adapter. The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a **ULONG** protocol offload identifier.

Remarks

NDIS and protocol drivers use the OID_PM_REMOVE_PROTOCOL_OFFLOAD OID to remove a protocol offload from the underlying network adapter.

The **DATA.SET_INFORMATION.InformationBuffer** member of the NDIS_OID_REQUEST structure must point to a **ULONG** value for a previously added protocol offload identifier. NDIS sets this protocol offload identifier in the **ProtocolOffloadId** member of the NDIS_PM_PROTOCOL_OFFLOAD structure when NDIS sent the prior OID_PM_ADD_PROTOCOL_OFFLOAD OID request to the underlying network adapter.

Remarks for miniport driver writers

NDIS ensures that the buffer size is at least **sizeof**(**ULONG**) and contains a valid protocol offload ID. Therefore, a miniport driver's *MiniportOidRequest* function should return NDIS_STATUS_SUCCESS for this request.

Note If the miniport driver is resetting, its *MiniportOidRequest* function should return NDIS_STATUS_NOT_ACCEPTED.

Return status codes

NDIS returns one of the following status codes for this request:

NDIS_STATUS_SUCCESS
The protocol offload was removed successfully.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_INVALID_LENGTH
The information buffer is too small. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required, in bytes.

NDIS_STATUS_FILE_NOT_FOUND
The protocol offload identifier in the OID request is not valid.

Requirements

Version	Supported in NDIS 6.20 and later. Mandatory for miniport drivers.
Header	Ntddndis.h (include Ndis.h)

OID_PM_ADD_PROTOCOL_OFFLOAD

OID_PM_REMOVE_WOL_PATTERN

Article • 02/18/2023

As a set, NDIS and protocol drivers use the OID_PM_REMOVE_WOL_PATTERN OID to remove a power management wake on LAN (WOL) pattern from a network adapter. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a ULONG pattern identifier.

Remarks

NDIS and protocol drivers use OID_PM_REMOVE_WOL_PATTERN to remove a wake on LAN (WOL) pattern from the underlying network adapter.

The **DATA.SET_INFORMATION.InformationBuffer** member of the **NDIS_OID_REQUEST** structure must point to a ULONG value for a previously added WOL pattern identifier. NDIS set this pattern identifier in the **PatternId** member of the **NDIS_PM_WOL_PATTERN** structure when NDIS sent the prior OID_PM_ADD_WOL_PATTERN OID request to the underlying network adapter.

Return Status Codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the **NdisMOidRequestComplete** function, passing **NDIS_STATUS_SUCCESS** for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

NDIS returns one of the following status codes for this request:

Term	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The NDIS version of the miniport driver is less than NDIS 6.20.
NDIS_STATUS_FILE_NOT_FOUND	The pattern identifier in the OID request is invalid.
NDIS_STATUS_INVALID_LENGTH	The information buffer is too small. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Requirements

Version	Supported in NDIS 6.20 and later. Mandatory for miniport drivers.
Header	Ntddndis.h (include Ndis.h)

NDIS_PM_WOL_PATTERN

OID_PM_ADD_WOL_PATTERN

NDIS_STATUS_PM_WOL_PATTERN_REJECTED

OID_PM_WOL_PATTERN_LIST

Article • 02/18/2023

As a query, overlying drivers can use the OID_PM_WOL_PATTERN_LIST OID to enumerate the wake on LAN patterns that are set on an underlying network adapter. After a successful return from the query, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a list of NDIS_PM_WOL_PATTERN structures that describe the currently added WOL patterns.

Remarks

NDIS handles the query for miniport drivers. NDIS drivers can use the OID_PM_WOL_PATTERN_LIST OID to get a list of wake on LAN patterns that are set on an underlying network adapter.

For each NDIS_PM_WOL_PATTERN structure in the list, NDIS sets the **NextWoLPatternOffset** member to the offset from the beginning of the OID information buffer (that is, the beginning of the buffer that the **InformationBuffer** member of the NDIS_OID_REQUEST structure points to) to the beginning of the next **NDIS_PM_WOL_PATTERN** structure in the list. The offset in the **NextWoLPatternOffset** member of the last structure in the list is zero.

For offsets in an NDIS_PM_WOL_PATTERN structure other than **NextWoLPatternOffset** (for example, **NameBufferOffset**), NDIS provides offsets that are relative to the beginning of each **NDIS_PM_WOL_PATTERN** structure.

If there are no WOL patterns that are set on the network adapter, NDIS sets the **DATA.QUERY_INFORMATION.BytesWritten** member of the NDIS_OID_REQUEST structure to zero and returns **NDIS_STATUS_SUCCESS** for the request. The data within the **DATA.QUERY_INFORMATION.InformationBuffer** member is not modified by NDIS.

NDIS returns one of the following status codes for the request:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** contains a pointer to a list of WOL patterns, if any.

NDIS_STATUS_PENDING
The request is pending completion. The final status code and results will be passed to the OID request completion handler of the caller.

NDIS_STATUS_BUFFER_TOO_SHORT
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for reasons other than the preceding reasons.

Requirements

Version	Supported in NDIS 6.20 and later. Not requested for miniport drivers. (See Remarks section.)

OID_PM_REMOVE_WOL_PATTERN

OID_PNP_WAKE_UP_PATTERN_LIST

OID_PNP_ADD_WAKE_UP_PATTERN

Article • 02/18/2023

The OID_PNP_ADD_WAKE_UP_PATTERN OID is sent by a protocol driver to a miniport driver to specify a wake-up pattern. The wake-up pattern, along with its mask, is described by an **NDIS_PM_PACKET_PATTERN** structure.

A protocol that enables pattern-match wake-up for a miniport driver (see OID_PNP_ENABLE_WAKE_UP) uses OID_PNP_ADD_WAKE_UP_PATTERN to specify a wake-up pattern. The wake-up pattern can be stored in host memory or on the network adapter, depending on the capabilities of the network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the following:

- An **NDIS_PM_PACKET_PATTERN** structure that provides information about the pattern and its mask.

- A mask that indicates which bytes of an incoming packet should be compared with corresponding bytes in the pattern. The mask starts with the first byte of the packet. The mask immediately follows the **NDIS_PM_PACKET_PATTERN** structure in the *InformationBuffer*. For more information about how this mask works, see the Network Device Class Power Management Reference specification.

- A wake-up pattern, which begins **PatternOffset** bytes from the beginning of the *InformationBuffer*. For more information about wake-up patterns, see the Network Device Class Power Management Reference specification.

The number of wake-up patterns that the miniport driver can accept from a protocol might depend on the availability of resources, such as the host memory that the miniport driver has allocated for such patterns, or the available storage in the network adapter. If a miniport driver cannot add a wake-up pattern due to insufficient resources, the miniport driver returns **NDIS_STATUS_RESOURCES** in response to OID_PNP_ADD_WAKE_UP_PATTERN.

If a protocol driver tries to add a duplicate pattern, the miniport driver should return **NDIS_STATUS_INVALID_DATA** in response to OID_PNP_ADD_WAKE_UP_PATTERN.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling **NdisRequest** or **NdisCoRequest**.

Requirements

Version	Supported in NDIS 6.0 and NDIS 6.1. For NDIS 6.20 and later, use OID_PM_ADD_WOL_PATTERN instead.
Header	Ntddndis.h (include Ndis.h)

NDIS_PM_PACKET_PATTERN

OID_PM_ADD_WOL_PATTERN

OID_PNP_CAPABILITIES

Article • 02/18/2023

The OID_PNP_CAPABILITIES OID requests a miniport driver to return the wake-up capabilities of its network adapter or requests an intermediate driver to return the intermediate driver's wake-up capabilities. The wake-up capabilities are formatted as an **NDIS_PNP_CAPABILITIES** structure, which is defined as follows:

C++

```
    typedef struct _NDIS_PNP_CAPABILITIES {
         ULONG Flags;
         NDIS_PM_WAKE_UP_CAPABILITIES WakeUpCapabilities;
    } NDIS_PNP_CAPABILITIES, *PNDIS_PNP_CAPABILITIES;
```

The members of this structure contain the following information:

Flags

NDIS_DEVICE_WAKE_UP_ENABLE

NDIS sets this flag if the underlying miniport driver supports one or more wake-up capabilities. Protocol drivers can test this flag to determine whether an underlying miniport driver has wake-up capabilities. Miniport drivers should not access this flag.

WakeUpCapabilities

An **NDIS_PM_WAKE_UP_CAPABILITIES** structure that specifies the wake-up capabilities of the miniport driver's network adapter. The **NDIS_PM_WAKE_UP_CAPABILITIES** structure is defined as follows:

C++

```
typedef struct _NDIS_PM_WAKE_UP_CAPABILITIES {
         NDIS_DEVICE_POWER_STATE MinMagicPacketWakeUp;
         NDIS_DEVICE_POWER_STATE MinPatternWakeUp;
         NDIS_DEVICE_POWER_STATE MinLinkChangeWakeUp;
       } NDIS_PM_WAKE_UP_CAPABILITIES, *PNDIS_PM_WAKE_UP_CAPABILITIES;
```

The members of this structure contain the following information:

MinMagicPacketWakeUp

Specifies the lowest device power state from which the miniport driver's network adapter can signal a wake-up on receipt of a magic packet. (A *magic packet* is a packet that contains 16 contiguous copies of the receiving network adapter's Ethernet address.)

The device power state is specified as one of the following NDIS_DEVICE_POWER_STATE values:

NdisDeviceStateUnspecified
The network adapter does not support magic-packet wake-ups.

NdisDeviceStateD0
The network adapter can signal a magic-packet wake-up from device power state D0. Because D0 is the fully powered state, this does not cause a wake-up but can be used as a run-time event.

NdisDeviceStateD1
The network adapter can signal a magic-packet wake-up from device power states D1 and D0.

NdisDeviceStateD2
The network adapter can signal a magic-packet wake-up from device states D2, D1, and D0.

NdisDeviceStateD3
The network adapter can signal a magic-packet wake-up from device power states D3, D2, D1, and D0.

MinPatternWakeUp
Specifies the lowest device power state from which the miniport driver's network adapter can signal a wake-up event on receipt of a network frame that contains a pattern specified by the protocol driver. The power state is specified as one of the following NDIS_DEVICE_POWER_STATE values:

NdisDeviceStateUnspecified
The network adapter does not support pattern-match wake-ups.

NdisDeviceStateD0
The network adapter can signal a pattern-match wake-up from device power state D0. Because D0 is the fully powered state, this does not cause a wake-up but can be used as a run-time event.

NdisDeviceStateD1
The network adapter can signal a pattern-match wake-up from device power states D1 and D0.

NdisDeviceStateD2
The network adapter can signal a pattern-match wake-up from device power states D2, D1, and D0.

NdisDeviceStateD3
The network adapter can signal a pattern-match wake-up from device power states D3, D2, D1, and D0.

MinLinkChangeWakeUp
Reserved. NDIS ignores this member.

For Miniport Drivers

After the miniport driver completes initialization, both the protocol driver and NDIS can query the miniport driver with this OID to determine the following:

- Whether the miniport driver is PM-aware.
- The network adapter's capabilities of indicating network wake-up events.

If the miniport driver returns **NDIS_STATUS_SUCCESS** to a query of OID_PNP_CAPABILITIES, NDIS considers the miniport driver to be PM-aware. If the miniport driver returns **NDIS_STATUS_NOT_SUPPORTED**, NDIS considers the miniport driver to be a legacy miniport driver that is not PM-aware.

When calling **NdisMSetAttributesEx**, a miniport driver that does not support wake-up capabilities but that can save and restore its network adapter state across a power-state transition can set the **NDIS_ATTRIBUTE_NO_HALT_ON_SUSPEND** flag. Setting this flag prevents NDIS from calling the driver's *MiniportHalt* function before the system transitions to a low-power (sleeping) state. However, if the miniport driver returns **NDIS_STATUS_NOT_SUPPORTED** in response to a query OID_PNP_CAPABILITIES, NDIS ignores the **NDIS_ATTRIBUTE_NO_HALT_ON_SUSPEND** flag and halts the network adapter if the system goes into a low-power state.

A miniport driver's network adapter can support any combination of wake-up events, including no wake-up events. A miniport driver can still support power management even if its network adapter cannot not signal wake-up events. In this case, the only power management OIDs that the miniport driver supports in addition to OID_PNP_CAPABILITIES are OID_PNP_QUERY_POWER and OID_PNP_SET_POWER.

If a miniport driver's network adapter does not support a particular wake-up event, the miniport driver should indicate an **NDIS_DEVICE_POWER_STATE** value of **NdisDeviceStateUnspecified** for the wake-up event in the **NDIS_PM_WAKE_UP_CAPABILITIES** structure.

OID_PNP_CAPABILITIES only indicates the wake-up capabilities of a miniport driver' s network adapter; it does not enable such capabilities. OID_PNP_ENABLE_WAKE_UP is used to enable a network adapter's wake-up capabilities.

For Intermediate Drivers

If the underlying network adapter is PM-aware, the intermediate driver should return **NDIS_STATUS_SUCCESS** to a query of OID_PNP_CAPABILITIES. In the **NDIS_PM_WAKE_UP_CAPABILITIES** structure returned by this OID, the intermediate driver should specify a device power state of **NdisDeviceStateUnspecified** for each wake-up capability (**MinMagicPacketWakeUp** or **MinPatternWakeUp**). Such a response indicates that the intermediate driver is PM-aware but does not manage a physical device.

If the underlying network adapter is not PM-aware, the intermediate driver should return **NDIS_STATUS_NOT_SUPPORTED** to a query of OID_PNP_CAPABILITIES.

Note For information about how NDIS 6.20 and later miniport drivers report power management capabilities, see Reporting Power Management Capabilities.

Requirements

Version	Supported in NDIS 6.0 and NDIS 6.1. For NDIS 6.20 and later, use OID_PM_CURRENT_CAPABILITIES instead.
Header	Ntddndis.h (include Ndis.h)

OID_PNP_ENABLE_WAKE_UP

Article • 02/18/2023

As a set, the OID_PNP_ENABLE_WAKE_UP OID specifies the wake-up capabilities that a miniport driver should enable in a network adapter.

As a query, OID_PNP_ENABLE_WAKE_UP obtains the current wake-up capabilities that are enabled for a network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure is a bitmask of flags that can be used to enable a combination of wake-up events:

NDIS_PNP_WAKE_UP_MAGIC_PACKET
When set, specifies that the miniport driver should enable a network adapter to signal a wake-up event on receipt of a magic packet. (A *magic packet* is a packet that contains 16 contiguous copies of the receiving network adapter's Ethernet address.) When cleared, specifies that the miniport driver should disable the network adapter from signaling such a wake-up event.

NDIS_PNP_WAKE_UP_PATTERN_MATCH
When set, specifies that the miniport driver should enable a network adapter to signal a wake-up event on receipt of a packet that contains a pattern specified by the protocol with OID_PNP_ADD_WAKE_UP_PATTERN. When cleared, specifies that the miniport driver should disable the network adapter from signaling such a wake-up event.

NDIS_PNP_WAKE_UP_LINK_CHANGE
Reserved. NDIS ignores this flag.

A protocol driver uses the network adapter's wake-up capabilities in **NDIS_BIND_PARAMETERS** to enable the associated network adapter's wake-up capabilities. A protocol driver can also query this OID to determine which wake-up capabilities are enabled for a network adapter.

NDIS does not immediately enable the wake-up capabilities that a protocol driver specifies. Instead, NDIS keeps tracks of the wake-up capabilities that the protocol driver enabled and, just before the network adapter transitions to a low-power state, NDIS sends an OID_PNP_ENABLE_WAKE_UP set request to the miniport driver to enable the appropriate wake-up events.

Before the network adapter transitions to a low-power state (that is, before NDIS sends the miniport driver an OID_PNP_SET_POWER request), NDIS sends the miniport driver an OID_PNP_ENABLE_WAKE_UP request to enable the appropriate wake-up capabilities.

The miniport driver must take the appropriate device-dependent steps to enable or disable wake-up events on the network adapter.

The miniport driver should clear the wake-up capabilities that NDIS set with OID_PNP_ENABLE_WAKE_UP when the system is resumed. The wake-up capabilities should not be persisted across resumes. If wake-up capabilities are enabled, NDIS explicitly sets OID_PNP_ENABLE_WAKE_UP before the miniport transitions to the low-power state.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling the **NdisOidRequest** or **NdisCoOidRequest** function.

Requirements

Version	Supported in NDIS 6.0 and 6.1. For NDIS 6.20 and later, use OID_PM_PARAMETERS instead).

OID_PNP_QUERY_POWER

Article • 02/18/2023

The OID_PNP_QUERY_POWER OID requests the miniport driver to indicate whether it can transition its network adapter to the low-power state specified in the *InformationBuffer*. The low-power state is specified as one of the following NDIS_DEVICE_POWER_STATE values:

NdisDeviceStateD1
This specifies a device state of D1.

NdisDeviceStateD2
This specifies a device state of D2.

NdisDeviceStateD3
This specifies a device state of D3.

An OID_PNP_QUERY_POWER request is not used to request a transition to a device state of D0. NDIS simply sends an OID_PNP_SET_POWER request that specifies a device state of D0.

By returning NDIS_STATUS_SUCCESS to this OID request, the miniport driver guarantees that it will transition the network adapter to the specified device power state on receipt of a subsequent OID_PNP_SET_POWER request. The miniport driver, in this case, must do nothing to jeopardize the transition.

Miniport drivers must always return NDIS_STATUS_SUCCESS to this OID request. Any other return code is an error.

An OID_PNP_QUERY_POWER request is always followed by an OID_PNP_SET_POWER request. The OID_PNP_SET_POWER request may immediately follow the OID_PNP_QUERY_POWER request or may arrive at an unspecified interval after the OID_PNP_QUERY_POWER request. A device state of D0 specified in the OID_PNP_SET_POWER request effectively cancels the OID_PNP_QUERY_POWER request.

An intermediate driver must always return NDIS_STATUS_SUCCESS to a query of OID_PNP_QUERY_POWER. An intermediate driver should never propagate an OID_PNP_QUERY_POWER request to an underlying miniport driver.

Requirements

Version	Supported for NDIS 5.1, and NDIS 6.0 and later.

Header	Ntddndis.h (include Ndis.h)

OID_PNP_REMOVE_WAKE_UP_PATTERN

Article • 02/18/2023

The OID_PNP_REMOVE_WAKE_UP_PATTERN OID requests the miniport driver to delete a wake-up pattern that it previously received in an OID_PNP_ADD_WAKE_UP_PATTERN request. The wake-up pattern, along with its mask, is described by an **NDIS_PM_PACKET_PATTERN** structure.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the following:

- An **NDIS_PM_PACKET_PATTERN** structure that provides information about the pattern and its mask.
- A mask that indicates which bytes of an incoming packet should be compared with corresponding bytes in the pattern. The mask starts with the first byte of the packet. The mask immediately follows the **NDIS_PM_PACKET_PATTERN** structure in the **InformationBuffer**.
- A wake-up pattern, which begins **PatternOffset** bytes from the beginning of the **InformationBuffer**.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling Ndis(Co)Request.

Requirements

Version	Supported in NDIS 6.0 and 6.1. For NDIS 6.20 and later, use OID_PM_REMOVE_WOL_PATTERN instead.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_PM_PACKET_PATTERN

OID_PNP_ADD_WAKE_UP_PATTERN

OID_PM_REMOVE_WOL_PATTERN

OID_PNP_SET_POWER

Article • 02/18/2023

The OID_PNP_SET_POWER OID notifies a miniport driver that its underlying network adapter will be transitioning to the device power state specified in the *InformationBuffer*. The device power state is specified as one of the following NDIS_DEVICE_POWER_STATE values:

- **NdisDeviceStateD0**
- **NdisDeviceStateD1**
- **NdisDeviceStateD2**
- **NdisDeviceStateD3**

An OID_PNP_SET_POWER request may be preceded by an OID_PNP_QUERY_POWER request.

Starting with NDIS 6.30, NDIS will not pause and restart the NDIS drivers in the driver stack during power-state transitions if the following conditions are true:

- The underlying miniport driver sets the **NDIS_MINIPORT_ATTRIBUTES_NO_PAUSE_ON_SUSPEND** flag in the NDIS_MINIPORT_ADAPTER_REGISTRATION_ATTRIBUTES structure. The driver passes a pointer to this structure in its call to the NdisMSetMiniportAttributes function.

- All overlying filter drivers that are attached to the miniport driver support NDIS 6.30 or later versions of NDIS.

- All overlying protocol drivers that are bound to the miniport driver support NDIS 6.30 or later versions of NDIS.

Transitioning to a Low-Power State (D1-D3)

When the miniport driver handles a set request of OID_PNP_SET_POWER to transition to a low-power state, it must do the following:

- Fully prepare the network adapter for the indicated network device power state. The task that is performed by the miniport driver to accomplish this is device-dependent.

- Wait for calls to the NdisMIndicateReceiveNetBufferLists function to return.

- Wait for send requests processed by the network adapter to complete. Once completed, the miniport driver must call the NdisMSendNetBufferListsComplete function. The driver should set the **Status** member in each NET_BUFFER_LIST structure to the appropriate NDIS_STATUS_*Xxx* value.

- Complete all pending send requests by calling the NdisMSendNetBufferListsComplete function. The driver must set the **Status** member in each NET_BUFFER_LIST structure to **NDIS_STATUS_LOW_POWER_STATE**.

- Reject all new send requests made to its *MiniportSendNetBufferLists* function immediately by calling the NdisMSendNetBufferListsComplete function. The driver must set the **Status** member in each NET_BUFFER_LIST structure to **NDIS_STATUS_LOW_POWER_STATE**.

The miniport driver that supports NDIS 6.30 and later versions of NDIS must also do the following:

- Not wait for the completion of pending receive indications through calls to its *MiniportReturnNetBufferLists* function. Also, the miniport driver must not alter the NET_BUFFER_LIST structure or data for any packets that are waiting to be completed.

- Handle the OID_PNP_SET_POWER request to a low-power state from either the Paused or Running adapter states. For more information about these states, see Miniport Adapter States and Operations.

Before the network adapter transitions to the D3 state, the miniport driver must turn off everything under the miniport driver's control by performing the following tasks:

- Disable interrupts and the DMA engine on the network adapter.

- Stop the receive engine on the network adapter.

- Do not deallocate or modify receive descriptors and packet buffers that are associated with pending receive indications.

- Cancel all NDIS timers.

Note A miniport driver cannot access the network adapter after the bus driver has transitioned the network adapter to the D3 state.

Transitioning to the Full-Power State (D0)

When the miniport driver handles a set request of OID_PNP_SET_POWER to transition to a full-power state, it must restore the receive engine of the network adapter to the same state that the receive engine was in before the adapter was transitioned to the low-power state.

Note The miniport driver must not access or change any receive buffers that are associated with pending receive indications.

NDIS calls the miniport driver's *MiniportRestart* function after the transition to a full-power state only if NDIS called the driver's *MiniportPause* function before the transition to a low-power state.

Note An intermediate driver must always return **NDIS_STATUS_SUCCESS** to a query of OID_PNP_SET_POWER. An intermediate driver should never propagate an OID_PNP_SET_POWER request to an underlying miniport driver.

Return status codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the **NdisMOidRequestComplete** function, passing NDIS_STATUS_SUCCESS for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.

Requirements

Version	Supported for NDIS 5.1, and NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

OID_PNP_WAKE_UP_ERROR

Article • 02/18/2023

The optional OID_PNP_WAKE_UP_ERROR OID indicates the number of false wake-ups that are signaled by the miniport driver's network adapter. A false wake-up occurs when the network adapter wakes up the system when it shouldn't have. For example, the network adapter could erroneously wake up the system due to an inexact pattern match.

The data type for this OID is a ULONG value.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling Ndis(Co)Request.

Requirements

Version	Supported for NDIS 5.1, and NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

OID_PNP_WAKE_UP_OK

Article • 02/18/2023

The optional OID_PNP_WAKE_UP_OK OID indicates the number of valid wake-ups that are signaled by the miniport driver's NIC. A valid wake-up occurs when the NIC wakes up the system in response to a valid pattern match or magic packet.

The data type for this OID is a ULONG value.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling Ndis(Co)Request.

Requirements

Version	Supported for NDIS 5.1, and NDIS 6.0 and later.
Header	Ntddndis.h (include Ndis.h)

OID_PNP_WAKE_UP_PATTERN_LIST

Article • 02/18/2023

The OID_PNP_WAKE_UP_PATTERN_LIST OID is used by a protocol to query a list of the wake-up patterns currently set for the miniport driver's network adapter. A protocol specifies a wake-up pattern with OID_PNP_ADD_WAKE_UP_PATTERN.

OID_PNP_WAKE_UP_PATTERN_LIST is handled by NDIS rather than the miniport driver.

NDIS returns to the protocol a description of each wake-up pattern set in the miniport driver. Each wake-up pattern, along with its mask, is described by an **NDIS_PM_PACKET_PATTERN** structure.

For each wake-up pattern, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains the following:

- An **NDIS_PM_PACKET_PATTERN** structure that provides information about the pattern and its mask.
- A mask that indicates which bytes of an incoming packet should be compared with corresponding bytes in the pattern. The mask starts with the first byte of the packet. The mask immediately follows the **NDIS_PM_PACKET_PATTERN** structure in the **InformationBuffer**.
- A wake-up pattern, which begins **PatternOffset** bytes from the beginning of the **InformationBuffer**.

An intermediate driver in which the upper edge receives this OID request must always propagate the request to the underlying miniport driver by calling Ndis(Co)Request.

Requirements

Version	Supported in NDIS 6.0 and 6.1. For NDIS 6.20 and later, use OID_PM_WOL_PATTERN_LIST instead.
Header	Ntddndis.h (include Ndis.h)

OID_QOS_CURRENT_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_QOS_CURRENT_CAPABILITIES to obtain the currently enabled NDIS Quality of Service (QoS) hardware capabilities of a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_QOS_CAPABILITIES structure.

Note This OID query request is handled by NDIS for miniport drivers that support the IEEE 802.1 Data Center Bridging (DCB) interface.

Remarks

Miniport drivers register the currently-enabled NDIS QoS hardware capabilities of a network adapter when its *MiniportInitializeEx* function is called. The driver registers these capabilities by following these steps:

1. The driver initializes an NDIS_QOS_CAPABILITIES structure with the enabled QoS hardware capabilities.
2. The driver sets the **CurrentQosCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the NDIS_QOS_CAPABILITIES structure.
3. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

Note NDIS does not report the currently-enabled NDIS QoS hardware capabilities of a network adapter to overlying protocol and filter drivers during the bind or attach operations.

For more information on how to register NDIS QoS capabilities, see Registering NDIS QoS Capabilities.

Return Status Codes

NDIS handles the OID query request of OID_QOS_CURRENT_CAPABILITIES request for miniport drivers, and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_QOS_CAPABILITIES). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_QOS_CAPABILITIES

OID_QOS_HARDWARE_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_QOS_HARDWARE_CAPABILITIES to obtain the NDIS Quality of Service (QoS) hardware capabilities of a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_QOS_CAPABILITIES structure.

Note This OID query request is handled by NDIS for miniport drivers that support the IEEE 802.1 Data Center Bridging (DCB) interface.

Remarks

The NDIS_QOS_CAPABILITIES structure contains information about the NDIS QoS hardware capabilities of a network adapter. These capabilities can include hardware capabilities that are currently disabled by INF file settings or through the **Advanced** properties page.

Note All the NDIS QoS hardware capabilities of a network adapter are returned through an OID query request of OID_QOS_HARDWARE_CAPABILITIES, regardless of whether a capability is enabled or disabled.

Miniport drivers registers the NDIS QoS hardware capabilities of a network adapter when its *MiniportInitializeEx* function is called. The driver registers these capabilities by following these steps:

1. The driver initializes an NDIS_QOS_CAPABILITIES structure with the NDIS QoS hardware capabilities.

2. The driver sets the **HardwareQosCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the NDIS_QOS_CAPABILITIES structure.

3. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

Note NDIS does not report the NDIS QoS hardware capabilities of a network adapter to overlying protocol and filter drivers during the bind or attach operations.

For more information on how to register NDIS QoS capabilities, see Registering NDIS QoS Capabilities.

Return Status Codes

NDIS handles the OID query request of OID_QOS_HARDWARE_CAPABILITIES request for miniport drivers, and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_QOS_CAPABILITIES). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_QOS_OFFLOAD_CREATE_SQ

Article • 02/18/2023

Overlying drivers issue OID set requests of OID_QOS_OFFLOAD_CREATE_SQ to create a new Scheduler Queue (SQ) on the miniport adapter. The caller sets the **InformationBuffer** member of the NDIS_OID_REQUEST structure to contain a pointer to an NDIS_QOS_SQ_PARAMETERS structure. **NDIS_QOS_SQ_PARAMETERS** contains the parameters of the new SQ.

Remarks

NDIS_QOS_SQ_ID is a ULONG value that NDIS allocates and assigns for an SQ. This identifier is unique per miniport adapter. The value **NDIS_QOS_DEFAULT_SQ_ID** is not a valid SQ ID and means that no SQ is to be used.

Return Status Codes

NDIS handles the OID set request of OID_QOS_OFFLOAD_CREATE_SQ for miniport drivers and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_PARAMETER	The length of the **InformationBuffer** is less than NDIS_SIZEOF_QOS_SQ_PARAMETERS_REVISION_1 or the **SqId** field of NDIS_QOS_SQ_PARAMETERS in the **InformationBuffer** is **NDIS_QOS_DEFAULT_SQ_ID**.
NDIS_STATUS_Xxx	The request failed for other reasons.

OID_QOS_OFFLOAD_UPDATE_SQ

Article • 02/18/2023

Overlying drivers issue OID set requests of OID_QOS_OFFLOAD_UPDATE_SQ to update a Scheduler Queue (SQ) on the miniport adapter. The caller should set the **InformationBuffer** member of the NDIS_OID_REQUEST structure to contain a pointer to an NDIS_QOS_SQ_PARAMETERS structure.

The caller should set the **SqId** field of **NDIS_QOS_SQ_PARAMETERS** to the current SQ ID of the SQ it wants to update. The caller should set the rest of the fields to the full set of parameters it desires on this SQ, except the **SqType** field which cannot be updated.

Remarks

Return Status Codes

NDIS handles the OID set request of OID_QOS_OFFLOAD_UPDATE_SQ for miniport drivers and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_PARAMETER	The length of the **InformationBuffer** is less than NDIS_SIZEOF_QOS_SQ_PARAMETERS_REVISION_1.
NDIS_STATUS_Xxx	The request failed for other reasons.

Requirements

Requirement	Value

OID_QOS_OFFLOAD_CREATE_SQ

OID_QOS_OFFLOAD_DELETE_SQ

OID_QOS_OPERATIONAL_PARAMETERS

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_QOS_OPERATIONAL_PARAMETERS to obtain the current NDIS Quality of Service (QoS) operational parameters for a network adapter. The miniport driver configures the network adapter with the operational NDIS QoS parameters in order to perform QoS packet transmission.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_QOS_PARAMETERS structure.

Note This OID query request is handled by NDIS for miniport drivers that support the IEEE 802.1 Data Center Bridging (DCB) interface.

Remarks

When NDIS handles the OID query request of OID_QOS_OPERATIONAL_PARAMETERS successfully, it returns the operational NDIS QoS parameters that it had cached from the previous NDIS_STATUS_QOS_OPERATIONAL_PARAMETERS_CHANGE status indication that was issued by the miniport driver. The driver issues this status indication to report on the initial set of operational NDIS QoS parameters. The driver also issues this status indication whenever the operational NDIS QoS parameters change.

NDIS returns an NDIS_QOS_PARAMETERS structure that is initialized in the following way:

- If the miniport driver previously issued an NDIS_STATUS_QOS_OPERATIONAL_PARAMETERS_CHANGE status indication, NDIS caches the NDIS_QOS_PARAMETERS data and returns this data for the OID query request of OID_QOS_OPERATIONAL_PARAMETERS.

- If the miniport driver did not issue an NDIS_STATUS_QOS_OPERATIONAL_PARAMETERS_CHANGE status indication, NDIS returns an NDIS_QOS_PARAMETERS structure with all the members (with the exception of the **Header** member) set to zero.

For more information on operational NDIS QoS parameters, see Overview of NDIS QoS Parameters.

Return Status Codes

NDIS returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_QOS_PARAMETERS). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_QOS_PARAMETERS

OID_QOS_PARAMETERS

Article • 02/18/2023

The Data Center Bridging (DCB) component (Msdcb.sys) issues an object identifier (OID) method request of OID_QOS_PARAMETERS to configure the local NDIS Quality of Service (QoS) parameters on a network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_QOS_PARAMETERS** structure.

Note This OID method request is mandatory for miniport drivers that support NDIS QoS for the IEEE 802.1 Data Center Bridging (DCB) interface.

Remarks

Miniport drivers obtain the local NDIS QoS parameters through an OID method request of OID_QOS_PARAMETERS. These parameters define how the network adapter prioritizes transmit, or *egress*, packets. For more information about these parameters, see Overview of NDIS QoS Parameters.

Note Only the DCB component can issue an OID method request of OID_QOS_PARAMETERS. An overlying protocol or filter driver must not issue this OID. For more information on the DCB component, see NDIS QoS Architecture for Data Center Bridging.

The DCB component issues an OID_QOS_PARAMETERS request under the following conditions:

- The system administrator installs or uninstalls the Microsoft DCB server feature.

  For more information about the DCB server feature, see System-Provided DCB Components.

- The system administrator enables or disables the DCB server feature while the feature is still installed.

- The system administrator changes any of the DCB server feature parameters.

- The operating system starts or restarts while the DCB server feature is installed.

When the miniport driver handles the OID method request of OID_QOS_PARAMETERS, it must follow these guidelines:

- The miniport driver copies the data within the NDIS_QOS_PARAMETERS structure to its cache of local NDIS QoS parameters. The driver then resolves its operational NDIS QoS parameters based on its cache of local NDIS QoS parameters and its cache of NDIS QoS parameters that it received from a remote peer.

  For more information about how the miniport driver resolves its operational parameters, see Resolving Operational NDIS QoS Parameters.

- The miniport driver must not modify any data that is contained within the NDIS_QOS_PARAMETERS structure. The driver must complete the OID method request and return the original data within the **NDIS_QOS_PARAMETERS** structure.

- The **NDIS_QOS_PARAMETERS_WILLING** flag specifies whether the miniport driver enables or disables the local Data Center Bridging Exchange (DCBX) Willing state. The driver handles this flag in the following way:

  - If this flag is set, the miniport driver must enable the local DCBX Willing state. This allows the driver to be remotely configured with QoS settings. In this case, the driver resolves its operational QoS parameters based on the remote QoS parameters. The miniport driver can also resolve its operational QoS parameters based on any proprietary QoS settings that are defined by the independent hardware vendor (IHV).

  - If this flag is not set, the miniport driver must disable the local DCBX Willing state. This allows the driver to resolve its operational QoS parameters from its local QoS parameters instead of remote QoS parameters. The miniport driver must also disable or override any local QoS parameter for which the related **NDIS_QOS_PARAMETERS_*Xxx*_CONFIGURED** flag is not set.

    For example, the miniport driver can override an unconfigured local QoS parameter with its proprietary settings for the QoS parameter that is defined by the IHV. If there are no proprietary settings for local QoS parameters that are not specified with an **NDIS_QOS_PARAMETERS_*Xxx*_CONFIGURED** flag, the driver must disable the use of these QoS parameters on the network adapter.

    Note The driver can also override configured local QoS parameters if they compromise the QoS parameters used by protocols or technologies that are enabled on the network adapter. For example, the driver can override the local QoS parameters if the network adapter is enabled for remote boot through the Fibre Channel over Ethernet (FCoE) protocol.

  For more information about the local DCBX Willing state, see Managing the Local DCBX Willing State.

For more information on how the miniport driver overrides local QoS parameters, see Managing NDIS QoS Parameters.

Note Overriding the local QoS parameters should not cause the miniport driver to fail the OID method request of OID_QOS_PARAMETERS.

For more information on how the miniport driver manages the local QoS parameters, see Setting Local NDIS QoS Parameters.

Return Status Codes

The miniport driver returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_PENDING	The OID request is pending completion. When the miniport driver calls **NdisMOidRequestComplete**, NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is completed.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_PARAMETER	One or more members of the **NDIS_QOS_PARAMETERS** structure contain incorrect values.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than **sizeof**(**NDIS_QOS_PARAMETERS**). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

NDIS_STATUS_QOS_OPERATIONAL_PARAMETERS_CHANGE

NDIS_STATUS_QOS_REMOTE_PARAMETERS_CHANGE

OID_QOS_REMOTE_PARAMETERS

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_QOS_REMOTE_PARAMETERS to obtain the NDIS Quality of Service (QoS) parameters for a remote peer. The miniport driver uses these remote QoS parameters to resolve its operational NDIS QoS parameters. The driver configures the network adapter with the operational parameters in order to perform QoS packet transmission.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_QOS_PARAMETERS structure.

Note This OID query request is valid only for miniport drivers that support the IEEE 802.1 Data Center Bridging (DCB) interface.

Remarks

When NDIS handles the OID request of OID_QOS_REMOTE_PARAMETERS successfully, it returns the remote NDIS QoS parameters that it had cached from the previous NDIS_STATUS_QOS_REMOTE_PARAMETERS_CHANGE status indication that was issued by the miniport driver. The driver issues this status indication to report on the initial set of remote NDIS QoS parameters. The driver also issues this status indication whenever the remote NDIS QoS parameters change.

NDIS returns an NDIS_QOS_PARAMETERS structure that is initialized in the following way:

- If the miniport driver previously issued an NDIS_STATUS_QOS_REMOTE_PARAMETERS_CHANGE status indication, NDIS caches the NDIS_QOS_PARAMETERS data and returns this data for the OID query request of OID_QOS_REMOTE_PARAMETERS.

- If the miniport driver did not issue an NDIS_STATUS_QOS_REMOTE_PARAMETERS_CHANGE status indication, NDIS returns an NDIS_QOS_PARAMETERS structure with all the members (with the exception of the **Header** member) set to zero.

For more information on remote NDIS QoS parameters, see Overview of NDIS QoS Parameters.

Return Status Codes

NDIS returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver does not support the NDIS QoS interface.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_QOS_PARAMETERS). NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

NDIS_STATUS_QOS_REMOTE_PARAMETERS_CHANGE

OID_QOS_PARAMETERS

OID_RECEIVE_FILTER_ALLOCATE_QUEUE

Article • 02/18/2023

Overlying drivers issue object identifier (OID) method requests of OID_RECEIVE_FILTER_ALLOCATE_QUEUE to allocate a queue that has an initial set of configuration parameters.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_QUEUE_PARAMETERS structure. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure that has a new queue identifier.

Remarks

The OID method request of OID_RECEIVE_FILTER_ALLOCATE_QUEUE is optional for NDIS 6.20 and later miniport drivers. It is mandatory for miniport drivers that support the virtual machine queue (VMQ) interface.

The overlying driver initializes the NDIS_RECEIVE_QUEUE_PARAMETERS structure with its requested queue configuration. NDIS assigns a queue identifier in the **QueueId** member of the **NDIS_RECEIVE_QUEUE_PARAMETERS** structure and passes the method request to the miniport driver.

Note The overlying driver can set the **NDIS_RECEIVE_QUEUE_PARAMETERS_PER_QUEUE_RECEIVE_INDICATION** and **NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED** flags in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure. The other flags are not used for queue allocation.

After a miniport driver is issued an OID request of OID_RECEIVE_FILTER_ALLOCATE_QUEUE and handles it successfully, the queue is in the Paused state.

The overlying driver must use the queue identifier that NDIS provides in subsequent OID requests, for example, to modify the queue parameters or free the queue. The queue identifier is also included in the out-of-band (OOB) data on all NET_BUFFER_LIST structures that are associated with the queue. Drivers use the NET_BUFFER_LIST_RECEIVE_QUEUE_ID macro to retrieve the queue identifier in a **NET_BUFFER_LIST** structure.

When NDIS receives an OID request to allocate a receive queue, it verifies the queue parameters. After NDIS allocates the necessary resources and the queue identifier, it submits the OID request to the underlying miniport driver. The queue identifier is unique to the associated network adapter.

If the miniport driver can successfully allocate the necessary software and hardware resources for the receive queue, it completes the OID request by returning **NDIS_STATUS_SUCCESS**.

The miniport driver must retain the queue identifiers for the allocated receive queues. NDIS uses the queue identifier of a receive queue for subsequent calls to the miniport driver in order to set a receive filter on the receive queue, change the receive queue parameters, or free the receive queue.

After an overlying driver allocates one or more receive queues and optionally sets the initial filters, it must issue OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE set OID requests to notify the miniport driver that the allocation is complete for the current batch of receive queues.

The miniport driver must not retain any packets in a receive queue if there are no filters set on that queue. If either a queue never had any filters set or all the filters were cleared, the queue should be empty and any packets should be discarded. That is, the packets are not indicated up the driver stack or retained in the queue.

Overlying drivers use OID requests of OID_RECEIVE_FILTER_FREE_QUEUE to free queues that they allocate.

Return Status Codes

Either NDIS or the miniport driver returns one of the following status codes for the OID method request of OID_RECEIVE_FILTER_ALLOCATE_QUEUE.

Status code	Description
NDIS_STATUS_SUCCESS	The queue was allocated successfully. The information buffer contains the updated NDIS_RECEIVE_QUEUE_PARAMETERS structure.
NDIS_STATUS_PENDING	The request is pending completion. The final status code and results will be passed to an OID request completion handler of the caller.
NDIS_STATUS_INVALID_PARAMETER	One or more of the parameters that the overlying driver provided were not valid.

Status code	Description
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_NOT_SUPPORTED	The NDIS version of the miniport driver is earlier than version 6.20.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

OID_RECEIVE_FILTER_CLEAR_FILTER

Article • 02/18/2023

Overlying drivers issue OID set requests of OID_RECEIVE_FILTER_CLEAR_FILTER to clear a receive filter on a network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS** structure.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

The OID set request of OID_RECEIVE_FILTER_CLEAR_FILTER is mandatory for miniport drivers that support the NDIS packet coalescing, SR-IOV, or VMQ interface.

An overlying driver, such as an NDIS protocol or filter driver, uses the OID_RECEIVE_FILTER_CLEAR_FILTER set request to clear a previously set filter. Only the driver that set the receive filter can clear it.

The overlying driver clears a receive filter by setting the **FilterId** member of the **NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS** structure to the identifier for the filter. The driver obtained the filter identifier from an earlier OID method request of OID_RECEIVE_FILTER_SET_FILTER.

Additional Instructions for NDIS Packet Coalescing

The following point applies to miniport and overlying drivers that support NDIS packet coalescing:

- An overlying driver must clear all the receive filters that it set on the miniport driver before it unbinds or detaches from the driver.

Additional Guidelines for the SR-IOV Interface

The following points apply to miniport and overlying drivers that support the SR-IOV interface:

- An overlying driver must clear all the filters that it set on a SR-IOV VPort before it frees the VPort. The overlying driver must also clear all the filters that it set on the default VPort before it closes its binding to the network adapter.
- A miniport driver must not indicate packets on a nondefault VPort if it has completed the OID request of OID_RECEIVE_FILTER_CLEAR_FILTER to clear the last filter on the VPort.

  Note A miniport driver also must not indicate packets on a nondefault VPort if it has completed an OID request of OID_NIC_SWITCH_DELETE_VPORT to free the VPort.

Additional Guidelines for the VMQ Interface

The following points apply to miniport and overlying drivers that support the VMQ interface:

- An overlying driver must clear all the filters that it set on a VMQ receive queue before it frees the queue. The overlying driver must also clear all the filters that it set on the default or drop queues before it closes its binding to the network adapter.
- A miniport driver must not indicate packets on a receive queue if it has completed the OID request of OID_RECEIVE_FILTER_CLEAR_FILTER to clear the last filter on the receive queue.

  Note A miniport driver also must not indicate packets on a receive queue if it has completed an OID request of OID_RECEIVE_FILTER_FREE_QUEUE to free the receive queue.

Return status codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the NdisMOidRequestComplete function, passing **NDIS_STATUS_SUCCESS** for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport adapter has been surprise removed.

NDIS returns one of the following status codes for this request:

NDIS_STATUS_SUCCESS
The specified filter was cleared successfully.

NDIS_STATUS_PENDING
The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_FILE_NOT_FOUND
The filter identifier is not valid.

NDIS_STATUS_INVALID_LENGTH
The information buffer is too small. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS

OID_NIC_SWITCH_DELETE_VPORT

OID_RECEIVE_FILTER_FREE_QUEUE

OID_RECEIVE_FILTER_SET_FILTER

OID_RECEIVE_FILTER_CURRENT_CAPABILITIES

Article • 02/18/2023

Overlying drivers issue OID query requests of OID_RECEIVE_FILTER_CURRENT_CAPABILITIES to obtain the currently enabled receive filtering capabilities of a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

Starting with NDIS 6.20, miniport drivers register the currently enabled receive filtering hardware capabilities of the network adapter when its *MiniportInitializeEx* function is called. Miniport drivers register these capabilities by following these steps:

1. The driver initializes an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure with the currently enabled receive filtering hardware capabilities.
2. The driver initializes an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure and sets the **CurrentReceiveFilterCapabilities** member to a pointer to the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure.
3. The miniport driver calls the **NdisMSetMiniportAttributes** function and sets the *MiniportAttributes* parameter to a pointer to an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

Overlying protocol and filter drivers do not have to issue OID query requests of OID_RECEIVE_FILTER_CURRENT_CAPABILITIES. NDIS provides the currently enabled receive filtering capabilities to these drivers in the following way:

- NDIS provides the currently enabled receive filtering capabilities of an underlying network adapter to overlying protocol drivers in the **ReceiveFilterCapabilities** member of the NDIS_BIND_PARAMETERS structure during the bind operation.
- NDIS provides the currently enabled receive filtering capabilities of an underlying network adapter to overlying filter drivers in the **ReceiveFilterCapabilities** member of the NDIS_FILTER_ATTACH_PARAMETERS structure during the attach operation.

Return status codes

NDIS handles the OID query request of OID_RECEIVE_FILTER_CURRENT_CAPABILITIES for miniport drivers, and returns one of the following status codes:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an NDIS_RECEIVE_FILTER_CAPABILITIES structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS passes the final status code and results to the OID request completion handler of the caller after the request has completed.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED
The network adapter does not support receive filtering.

NDIS_STATUS_FAILURE
The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

NDIS_OID_REQUEST

NDIS_RECEIVE_FILTER_CAPABILITIES

OID_RECEIVE_FILTER_ENUM_FILTERS

Article • 02/18/2023

An overlying driver issues an OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS to obtain a list of all the filters that are configured on a network adapter.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_FILTER_INFO_ARRAY structure.

After a successful return from the OID method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer is formatted to contain the following:

- An NDIS_RECEIVE_FILTER_INFO_ARRAY structure that specifies a list of receive filters that are currently configured on a miniport driver.
- An array of NDIS_RECEIVE_FILTER_INFO structures. Each structure specifies the parameters of a receive filter that is currently configured on a miniport driver.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

Overlying drivers or applications issue OID method requests of OID_RECEIVE_FILTER_ENUM_FILTERS to enumerate the receive filters that were set on a network adapter. This includes receive filters that were set on an SR-IOV virtual port (VPort) or a VMQ receive queue.

Additional Guidelines for the NDIS Packet Coalescing Interface

Starting with Windows Server 2012, NDIS packet coalescing only supports the default receive queue of a network adapter.

To enumerate the packet coalescing receive filters, the overlying driver must set the **QueueId** member of the NDIS_RECEIVE_FILTER_INFO_ARRAY structure to NDIS_DEFAULT_RECEIVE_QUEUE_ID.

Additional Guidelines for the SR-IOV Interface

Starting with Windows Server 2012, the SR-IOV interface only supports the default receive queue of a virtual port (VPort).

To enumerate the VPort receive filters, the overlying driver must set the **QueueId** member of the NDIS_RECEIVE_FILTER_INFO_ARRAY structure to NDIS_DEFAULT_RECEIVE_QUEUE_ID.

Additional Guidelines for the VMQ Interface

An overlying driver can issue OID method requests of OID_RECEIVE_FILTER_ENUM_FILTERS to enumerate the receive filters that were set on a VMQ receive queue. When the overlying driver initializes the NDIS_RECEIVE_FILTER_INFO_ARRAY structure, it sets the **QueueId** member to one of the following values:

- The queue identifier value for a nondefault receive queue. The overlying driver obtained the queue identifier input value from an earlier OID method request of OID_RECEIVE_FILTER_ALLOCATE_QUEUE or an OID query request of OID_RECEIVE_FILTER_ENUM_QUEUES.
- The queue identifier value of NDIS_DEFAULT_RECEIVE_QUEUE_ID, which specifies the default receive queue.

Return status codes

NDIS handles the OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS for miniport drivers, and returns one of the following status codes:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an NDIS_RECEIVE_FILTER_INFO_ARRAY structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS passes the final status code and results to the OID request completion handler of the caller after the request has completed.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

OID_RECEIVE_FILTER_SET_FILTER

OID_RECEIVE_FILTER_ENUM_QUEUES

Article • 02/18/2023

Overlying drivers and user-mode applications issue object identifier (OID) query requests of OID_RECEIVE_FILTER_ENUM_QUEUES to obtain a list of all the receive queues that are allocated on a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_QUEUE_INFO_ARRAY structure that is followed by an NDIS_RECEIVE_QUEUE_INFO structure for each filter.

Remarks

NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_ALLOCATE_QUEUE and OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID requests.

Overlying drivers and user-mode applications issue OID query requests of OID_RECEIVE_FILTER_ENUM_QUEUES to enumerate the receive queues on a network adapter.

If a protocol driver issues the request, the request type inside the NDIS_OID_REQUEST structure is set to **NdisRequestQueryInformation** and this OID returns an array of all the receive queues that the protocol driver allocated on the network adapter. If a user-mode application issued the request, the request type inside the **NDIS_OID_REQUEST** structure is set to **NdisRequestQueryStatistics**, and this OID returns an array of information for all the receive queues on the network adapter.

Return Status Codes

NDIS handles the OID query request of OID_RECEIVE_FILTER_ENUM_QUEUES for miniport drivers, and returns one of the following status codes.

Status code	Description
NDIS_STATUS_SUCCESS	The request completed successfully. The **InformationBuffer** points to an NDIS_RECEIVE_QUEUE_INFO_ARRAY structure.

Status code	Description
NDIS_STATUS_PENDING	The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request has completed.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.

NDIS_RECEIVE_QUEUE_INFO

NDIS_RECEIVE_QUEUE_INFO_ARRAY

OID_RECEIVE_FILTER_ALLOCATE_QUEUE

OID_RECEIVE_FILTER_QUEUE_PARAMETERS

OID_RECEIVE_FILTER_FREE_QUEUE

Article • 02/18/2023

NDIS protocol drivers issue object identifier (OID) set requests of OID_RECEIVE_FILTER_FREE_QUEUE to free a receive queue.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_FREE_PARAMETERS** structure with a queue identifier of type **NDIS_RECEIVE_QUEUE_ID**.

Remarks

The OID set request of OID_RECEIVE_FILTER_FREE_QUEUE is optional for NDIS 6.20 and later miniport drivers. It is mandatory for miniport drivers that support the virtual machine queue interface.

After an overlying driver issues the OID_RECEIVE_FILTER_ALLOCATE_QUEUE OID to allocate a receive queue, it issues the OID_RECEIVE_FILTER_FREE_QUEUE OID to free the receive queue.

When NDIS requests a miniport driver to free a VMQ receive queue, it follows these steps:

1. The network adapter stops the DMA transfer of data to receive buffers that are associated with the receive queue, after which the queue must enter the DMA Stopped state. The network adapter probably stopped the DMA activity when it received the OID_RECEIVE_FILTER_CLEAR_FILTER OID request to clear the last set filter on the receive queue.

2. The miniport driver generates an **NDIS_STATUS_RECEIVE_QUEUE_STATE** status indication with the **QueueState** member of the **NDIS_RECEIVE_QUEUE_STATE** structure set to **NdisReceiveQueueOperationalStateDmaStopped** to notify NDIS that the DMA transfer has been stopped.

3. The miniport driver waits for all the indicated receive packets for that queue to be returned to the miniport driver.

4. The miniport driver frees all the shared memory that it allocated for the network adapter's receive buffers that are associated with the queue by calling **NdisFreeSharedMemory**.

5. The miniport driver completes the OID_RECEIVE_FILTER_FREE_QUEUE OID request to free the receive queue.

Miniport drivers call the **NdisFreeSharedMemory** function to free shared memory for a queue. If the miniport driver allocated the shared memory for a nondefault queue, the driver frees the shared memory in the context of the OID_RECEIVE_FILTER_FREE_QUEUE OID while it is freeing the queue. Miniport drivers free shared memory that they allocated for the default queue in the context of the *MiniportHaltEx* function.

An overlying driver must free all the filters that it set on a queue before it frees the queue. Also, an overlying driver must free all the receive queues that it allocated on a network adapter before it calls the **NdisCloseAdapterEx** function to close a binding to the network adapter. NDIS frees all the queues that are allocated on a network adapter before it calls the miniport driver's *MiniportHaltEx* function.

Return Status Codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the **NdisMOidRequestComplete** function, passing NDIS_STATUS_SUCCESS for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

NDIS returns one of the following status codes for this request:

Status code	Description
NDIS_STATUS_SUCCESS	The requested queue was freed successfully.

Status code	Description
NDIS_STATUS_PENDING	The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler for the caller after the request has completed.
NDIS_STATUS_INVALID_PARAMETER	The queue identifier is invalid.
NDIS_STATUS_INVALID_LENGTH	The information buffer is too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

OID_RECEIVE_FILTER_ALLOCATE_QUEUE

OID_RECEIVE_FILTER_GLOBAL_PARAMETERS

Article • 02/18/2023

Overlying drivers issue OID query requests of OID_RECEIVE_FILTER_GLOBAL_PARAMETERS to obtain the global receive filtering parameters of a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS** structure.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

Starting with NDIS 6.20, protocol drivers use OID_RECEIVE_FILTER_GLOBAL_PARAMETERS to query the current global configuration parameters for receive filtering on a network adapter. For example, protocol drivers can use this OID to determine whether types of receive filters or receive queues are enabled or disabled.

Return status codes

NDIS handles the OID query request of OID_RECEIVE_FILTER_GLOBAL_PARAMETERS for miniport drivers, and returns one of the following status codes:

NDIS_STATUS_SUCCESS
The request completed successfully.

NDIS_STATUS_PENDING
The request is pending completion. NDIS passes the final status code and results to the

OID request completion handler of the caller after the request is complete.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_INVALID_PARAMETER
The request failed because it tried to enable a capability that the underlying network adapter does not support.

NDIS_STATUS_FAILURE
The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS

OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES

Article • 02/18/2023

Overlying drivers issue OID query requests of OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES to obtain the receive filtering hardware capabilities of a network adapter.

After a successful return from the OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an**NDIS_RECEIVE_FILTER_CAPABILITIES** structure.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

The **NDIS_RECEIVE_FILTER_CAPABILITIES** structure contains information about the receive filtering hardware capabilities of a network adapter. These capabilities can include hardware capabilities that are currently disabled by INF file settings or through the **Advanced** properties page.

Note All the receive filtering hardware capabilities of a network adapter are returned through an OID query request of OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES, regardless of whether a capability is enabled or disabled.

Starting with NDIS 6.20, miniport drivers register the currently enabled receive filtering hardware capabilities of the network adapter when its *MiniportInitializeEx* function is called. Miniport drivers register these capabilities by following these steps:

1. The driver initializes an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure with the receive filtering hardware capabilities.

2. The driver initializes an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure and sets the **CurrentReceiveFilterCapabilities** member to a pointer to the NDIS_RECEIVE_FILTER_CAPABILITIES structure.

3. The miniport driver calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

Return status codes

NDIS handles the OID query request of OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES for miniport drivers, and returns one of the following status codes:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an NDIS_RECEIVE_FILTER_CAPABILITIES structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS passes the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. NDIS set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED
The network adapter does not support receive filtering.

NDIS_STATUS_FAILURE
The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_RECEIVE_FILTER_CAPABILITIES

OID_RECEIVE_FILTER_MOVE_FILTER

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_RECEIVE_FILTER_MOVE_FILTER to move a previously configured receive filter. Receive filters are moved from one virtual port (VPort) to a different VPort.

Overlying drivers issue this OID set request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID set request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS structure.

Remarks

NDIS validates the members of the NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS structure before it forwards the OID set request to the PF miniport driver.

The PF miniport driver must handle this OID set request atomically. The driver must be able to configure the network adapter to simultaneously remove the filter from a receive queue and VPort and set it on a different receive queue and VPort.

For more information, see Moving a Receive Filter to a Virtual Port.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID set request of OID_RECEIVE_FILTER_MOVE_FILTER.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS structure have invalid values.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is less than sizeof(NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS). The PF miniport driver must set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS

OID_RECEIVE_FILTER_PARAMETERS

Article • 02/18/2023

An overlying driver issues an OID method request of OID_RECEIVE_FILTER_PARAMETERS to obtain the current configuration parameters of a filter on a network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. NDIS uses the **FilterId** member in the input structure to identify the filter.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer. This buffer is formatted to contain the following:

- An **NDIS_RECEIVE_FILTER_PARAMETERS** structure that specifies the parameters for an NDIS receive filter.
- An array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures that specifies the filter test criterion for a field in a network packet header.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.
- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.
- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

Overlying drivers issue OID method requests of OID_RECEIVE_FILTER_PARAMETERS to obtain the configuration parameters for a receive filter that was set on a network adapter. This includes a receive filter that was set on a VMQ receive queue or SR-IOV virtual port (VPort), as well as a packet coalescing filter that was downloaded to the miniport driver.

The overlying driver obtained the filter identifier from an earlier OID method request of OID_RECEIVE_FILTER_SET_FILTER or from OID requests of OID_RECEIVE_FILTER_ENUM_FILTERS.

Return status codes

NDIS handles the OID request of OID_RECEIVE_FILTER_PARAMETERS for miniport drivers, and returns one of the following status codes:

NDIS_STATUS_SUCCESS
The request completed successfully. The **InformationBuffer** points to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure.

NDIS_STATUS_PENDING
The request is pending completion. NDIS passes the final status code and results to the OID request completion handler of the caller after the request is complete.

NDIS_STATUS_INVALID_PARAMETER
The overlying driver or application provided an invalid filter identifier. A filter identifier is not valid if it is zero or if it specifies an undefined filter.

NDIS_STATUS_INVALID_LENGTH
The information buffer was too short. NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.

NDIS_STATUS_FAILURE
The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

OID_RECEIVE_FILTER_ENUM_FILTERS

NDIS_RECEIVE_FILTER_PARAMETERS

OID_RECEIVE_FILTER_SET_FILTER

OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE

Article • 02/18/2023

NDIS protocol drivers issue object identifier (OID) method requests of OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE to notify the miniport driver that an allocation has completed for the current batch of receive queues.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_QUEUE_ALLOCATION_COMPLETE_ARRAY structure that is followed by an NDIS_RECEIVE_QUEUE_ALLOCATION_COMPLETE_PARAMETERS structure for each queue. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the same array of structures, and the **CompletionStatus** member of each **NDIS_RECEIVE_QUEUE_ALLOCATION_COMPLETE_PARAMETERS** structure contains the completion status for each queue.

Remarks

The OID method request of OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE is optional for NDIS 6.20 and later miniport drivers. It is mandatory for miniport drivers that support the virtual machine queue (VMQ) interface.

After allocating one or more receive queues and optionally setting the initial filters, the protocol driver must issue the OID method request of OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE in order to notify the miniport driver that the allocation has completed for the current batch of receive queues. This allows the miniport driver to balance the hardware resources among multiple receive queues; if necessary, it can allocate resources such as shared memory for the receive queues.

After a miniport driver receives an OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE request and it has filters that are set on the queue, the queue is in the Running state. In this state, the miniport driver can start indications of packets in the queue by calling NdisMIndicateReceiveNetBufferLists.

Return Status Codes

The miniport driver returns one of the following status codes for the OID method request of OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE.

Status code	Description
NDIS_STATUS_SUCCESS	The queue allocation has completed. The information buffer contains the updated NDIS_RECEIVE_QUEUE_ALLOCATION_COMPLETE_ARRAY structure and parameter structures with the completion status for the queue allocation.
NDIS_STATUS_PENDING	The request is pending completion. The final status code and results will be passed to the OID request completion handler of the caller.
NDIS_STATUS_INVALID_PARAMETER	One or more of the parameters that the overlying driver provided were not valid.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_NOT_SUPPORTED	The NDIS version of the miniport driver is earlier than version 6.20.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

OID_RECEIVE_FILTER_QUEUE_PARAMETERS

Article • 02/18/2023

Overlying drivers issue object identifier (OID) method requests of OID_RECEIVE_FILTER_QUEUE_PARAMETERS to obtain the current configuration parameters of a receive queue. The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_RECEIVE_QUEUE_PARAMETERS structure with a queue identifier of type **NDIS_RECEIVE_QUEUE_ID**. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure.

Overlying drivers issue OID set requests of OID_RECEIVE_FILTER_QUEUE_PARAMETERS to change the current configuration parameters of a queue. The overlying driver provides a pointer to an NDIS_RECEIVE_QUEUE_PARAMETERS structure in the **InformationBuffer** member of the NDIS_OID_REQUEST structure.

Remarks

Overlying drivers issue OID set requests of OID_RECEIVE_FILTER_QUEUE_PARAMETERS to change the parameters of one or more receive queues. The OID set request is optional for NDIS 6.20 and later miniport drivers. However, the OID request is mandatory for miniport drivers that support the virtual machine queue (VMQ) interface.

Note Only the overlying driver that allocated the queue can change the configuration parameters by issuing OID set requests of OID_RECEIVE_FILTER_QUEUE_PARAMETERS.

The overlying driver obtained the queue identifier input value from an earlier OID_RECEIVE_FILTER_ALLOCATE_QUEUE method OID request.

After the overlying driver allocates a queue, it can change the configuration parameters that have a corresponding change flag (NDIS_RECEIVE_QUEUE_PARAMETER_*Xxx*_CHANGED) in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure. However, after the queue has been allocated, the overlying driver cannot change the configuration parameters that do not have a corresponding change flag.

Return Status Codes

NDIS handles the OID method request of OID_RECEIVE_FILTER_QUEUE_PARAMETERS for miniport drivers, and returns one of the following status codes.

Status code	Description
NDIS_STATUS_SUCCESS	The request completed successfully.
NDIS_STATUS_PENDING	The request is pending completion. NDIS will pass the final status code and results to the OID request completion handler of the caller after the request has completed.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_INVALID_PARAMETER	The request failed because it tried to enable a capability that the underlying network adapter does not support.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_RECEIVE_QUEUE_PARAMETERS

OID_RECEIVE_FILTER_ALLOCATE_QUEUE

OID_RECEIVE_FILTER_QUEUE_PARAMETERS

OID_RECEIVE_FILTER_SET_FILTER

Article • 02/18/2023

An overlying driver issues an OID method request of OID_RECEIVE_FILTER_SET_FILTER to set a filter on a network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An **NDIS_RECEIVE_FILTER_PARAMETERS** structure that specifies the parameters for an NDIS receive filter.

- An array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures that specifies the filter test criterion for a field in a network packet header.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. If the overlying driver is creating a new receive filter, NDIS updates this structure with a new filter identifier.

Remarks

NDIS receive filters are used in the following NDIS interfaces:

- NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.

- Single Root I/O Virtualization (SR-IOV). For more information about how to use receive filters in this interface, see Setting a Receive Filter on a Virtual Port.

- Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

The OID method request of OID_RECEIVE_FILTER_SET_FILTER is mandatory for miniport drivers that support the NDIS packet coalescing, SR-IOV, or VMQ interface.

The overlying driver initializes the **NDIS_RECEIVE_FILTER_PARAMETERS** structure with its requested filter configuration. NDIS assigns a filter identifier in the **FilterId** member of the NDIS_RECEIVE_FILTER_PARAMETERS structure and passes the method request to the underlying miniport driver.

Each filter that is set on a receive queue has a unique filter identifier for a network adapter. That is, the filter identifiers are not duplicated on different queues that the network adapter manages. When NDIS receives an OID request to set a filter on a receive queue, it verifies the filter parameters. After NDIS allocates the necessary resources and the filter identifier, it submits the OID request to the underlying network adapter. If the network adapter can successfully allocate the necessary software and hardware resources for the filter, it completes the OID request with a return status of NDIS_STATUS_SUCCESS.

Note Starting with NDIS 6.30, packet coalescing receive filter are only supported on the default receive queue of the network adapter. This receive queue has an identifier of NDIS_DEFAULT_RECEIVE_QUEUE_ID.

The miniport driver must retain the filter identifiers for the allocated receive filters. NDIS uses the identifier of a filter in later OID requests to change the receive filter parameters or clear the receive filter.

After a miniport driver receives an OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE request and it has filters that are set on the queue, the queue is in the *Running* state. In this state, the miniport driver can start indications of packets in the queue by calling **NdisMIndicateReceiveNetBufferLists**.

Additional Guidelines for the SR-IOV Interface

The following points apply to miniport drivers that support the SR-IOV interface:

- For the SR-IOV interface, a receive queue is created on a default or nondefault virtual port (VPort).

  Note Starting with Windows Server 2012, the SR-IOV interface only supports the default receive queue of a VPort.

  After an SR-IOV VPort is allocated through an OID set request of OID_NIC_SWITCH_CREATE_VPORT, overlying drivers can set filters on the VPort with OID requests of OID_RECEIVE_FILTER_SET_FILTER.

  Note Only the overlying driver that allocated the VPort can set a filter on that VPort.

- Because the default VPort always exists, overlying drivers can always set a filter on the default VPort.

- When the VPort is created, no receive filters are set on it. In this case, the miniport driver must not indicate any receive packets on that VPort before the miniport driver receives an OID request of OID_RECEIVE_FILTER_SET_FILTER for the VPort.

After this OID request is issued, the miniport driver can indicate packets on that VPort.

Note If the miniport driver indicates packets on a VPort while it is processing an OID request of OID_RECEIVE_FILTER_SET_FILTER, it must complete the OID request and return an NDIS_STATUS_SUCCESS status code.

Additional Guidelines for the VMQ Interface

The following points apply to miniport drivers that support the VMQ interface:

- After a VMQ receive queue is allocated, overlying drivers can set filters on the receive queue with OID requests of OID_RECEIVE_FILTER_SET_FILTER.

  Note Only the protocol driver that allocated a receive queue can set a filter on that queue.

- Because the default queue always exists, overlying drivers can always set a filter on the default queue. If the network adapter supports a drop queue, overlying drivers can set a filter on the drop queue.

  Overlying drivers do not own the default or drop queues. Therefore, all protocol drivers that are bound to a network adapter use the default or drop queue.

- When the receive queue is created, no receive filters are set on it. In this case, the miniport driver must not indicate any receive packets on that receive queue before the miniport driver receives an OID request of OID_RECEIVE_FILTER_SET_FILTER for the receive queue. After this OID request is issued, the miniport driver can indicate packets on that receive queue.

  Note If the miniport driver indicates packets on a queue while it is processing an OID request of OID_RECEIVE_FILTER_SET_FILTER, it must complete the OID request and return an NDIS_STATUS_SUCCESS status code.

Return status codes

The miniport driver returns one of the following status codes for the OID method request of OID_RECEIVE_FILTER_SET_FILTER:

NDIS_STATUS_SUCCESS
The filter was set on the queue successfully. The information buffer contains the updated NDIS_RECEIVE_FILTER_PARAMETERS structure.

NDIS_STATUS_PENDING

The request is pending completion. The final status code and results will be passed to the OID request completion handler of the caller.

NDIS_STATUS_INVALID_PARAMETER

One or more of the parameters that the overlying driver provided was not valid.

NDIS_STATUS_INVALID_LENGTH

The information buffer was too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.

NDIS_STATUS_NOT_SUPPORTED

The NDIS version of the miniport driver is an earlier version than 6.20.

NDIS_STATUS_FAILURE

The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SRIOV_BAR_RESOURCES

Article • 02/18/2023

NDIS issues an object identifier (OID) method request of OID_SRIOV_BAR_RESOURCES to determine the memory resources that were allocated to a PCI Express (PCIe) Base Address Register (BAR) of a PCIe Virtual Function (VF).

NDIS issues this OID method request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following structures:

- An NDIS_SRIOV_BAR_RESOURCES_INFO structure that specifies the VF and BAR for which the PF miniport driver returns resource information.

- A CM_PARTIAL_RESOURCE_DESCRIPTOR structure which follows the NDIS_SRIOV_BAR_RESOURCES_INFO structure. The **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure contains information about the memory resources that were allocated to the specified BAR.

Remarks

NDIS issues an OID method request of OID_SRIOV_BAR_RESOURCES to obtain the system physical address and length of the memory resources that were allocated to a VF BAR. Before it issues the OID method request, NDIS formats the NDIS_SRIOV_BAR_RESOURCES_INFO structure in the following way:

- NDIS sets the **VFId** member of the NDIS_SRIOV_BAR_RESOURCES_INFO structure to the identifier associated with the VF.

- NDIS sets the **BarIndex** member of the NDIS_SRIOV_BAR_RESOURCES_INFO structure to the BAR index for the specified VF. The BAR index is the offset of the register within the table of BARs in the PCI configuration space.

- NDIS sets the **BarResourcesOffset** member of the NDIS_SRIOV_BAR_RESOURCES_INFO structure to the offset, in units of bytes, from the beginning of the **NDIS_SRIOV_BAR_RESOURCES_INFO** structure to a CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

Note Overlying drivers, such as protocol or filter drivers, cannot issue OID method requests of OID_SRIOV_BAR_RESOURCES to the PF miniport driver.

When the PF miniport driver receives the OID method request, the driver returns the resources for the specified BAR by formatting the CM_PARTIAL_RESOURCE_DESCRIPTOR structure within the **InformationBuffer** member of the NDIS_OID_REQUEST structure. The driver formats the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure with the system hardware resources associated with the BAR for the specified VF.

Note The driver must format the structure for a resource type of **CmResourceTypeMemory**.

Return Status Codes

The PF miniport driver returns one of the following status codes for the method request of OID_SRIOV_BAR_RESOURCES.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_BAR_RESOURCES_INFO structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer is less than (sizeof(NDIS_SRIOV_BAR_RESOURCES_INFO) + sizeof(CM_PARTIAL_RESOURCE_DESCRIPTOR). The PF miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

CM_PARTIAL_RESOURCE_DESCRIPTOR

NDIS_OID_REQUEST

NDIS_SRIOV_BAR_RESOURCES_INFO

OID_SRIOV_CURRENT_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_SRIOV_CURRENT_CAPABILITIES to obtain the current single root I/O virtualization (SR-IOV) capabilities of a network adapter.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to the NDIS_SRIOV_CAPABILITIES structure.

Remarks

Starting with NDIS 6.30, miniport drivers supply the enabled SR-IOV hardware capabilities on the network adapter when its *MiniportInitializeEx* function is called. The driver initializes an NDIS_SRIOV_CAPABILITIES structure with the currently enabled SR-IOV hardware capabilities and sets the **CurrentSriovCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the **NDIS_SRIOV_CAPABILITIES** structure. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

Overlying protocol and filter drivers do not have to issue OID query requests of OID_SRIOV_CURRENT_CAPABILITIES. NDIS provides the currently enabled SR-IOV capabilities of a network adapter to these drivers in the following way:

- NDIS reports the currently enabled SR-IOV capabilities of an underlying network adapter to overlying protocol drivers in the **SriovCapabilities** member of the NDIS_BIND_PARAMETERS structure during the bind operation.

- NDIS reports the currently enabled SR-IOV capabilities of an underlying network adapter to overlying filter drivers in the **SriovCapabilities** member of the NDIS_FILTER_ATTACH_PARAMETERS structure during the attach operation.

Return Status Codes

NDIS handles the OID query request of the OID_SRIOV_CURRENT_CAPABILITIES request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_SRIOV_CURRENT_CAPABILITIES request, it returns one of the following status codes:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The miniport driver must set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SRIOV_HARDWARE_CAPABILITIES

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_SRIOV_HARDWARE_CAPABILITIES to obtain the single root I/O virtualization (SR-IOV) hardware capabilities of the network adapter.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to the NDIS_SRIOV_CAPABILITIES structure.

Remarks

The NDIS_SRIOV_CAPABILITIES structure contains information about the hardware capabilities of the network adapter, such as whether the adapter supports SR-IOV and whether the miniport driver is managing the adapter's PCI Express (PCIe) Physical Function (PF) or Virtual Function (VF). These capabilities can include the hardware capabilities that are currently disabled by the INF file settings or through the **Advanced** properties page.

Note All the SR-IOV capabilities of the network adapter are returned through an OID query request of OID_SRIOV_HARDWARE_CAPABILITIES, regardless of whether a capability is enabled or disabled.

Starting with NDIS 6.30, miniport drivers supply the SR-IOV hardware capabilities when its *MiniportInitializeEx* function is called. The driver initializes an NDIS_SRIOV_CAPABILITIES structure with the SR-IOV hardware capabilities and sets the **HardwareSriovCapabilities** member of the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure to a pointer to the **NDIS_SRIOV_CAPABILITIES** structure. The miniport driver then calls the NdisMSetMiniportAttributes function and sets the *MiniportAttributes* parameter to a pointer to an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

Return Status Codes

NDIS handles the OID query request of the OID_SRIOV_HARDWARE_CAPABILITIES request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_SRIOV_HARDWARE_CAPABILITIES request, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The miniport driver must set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SRIOV_PF_LUID

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_SRIOV_PF_LUID to receive the locally unique identifier (LUID) associated with the PCI Express (PCIe) Physical Function (PF) of the network adapter.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to the NDIS_SRIOV_PF_LUID_INFO structure.

Remarks

NDIS generates a LUID for the PF before NDIS calls the *MiniportInitializeEx* function of the miniport driver for the PF. This LUID is valid until NDIS calls the *MiniportHaltEx* function of the driver.

Note The value of the **Luid** member differs from the **NetLuid** member of the NDIS_MINIPORT_INIT_PARAMETERS structure. This structure is passed to the miniport driver through the *MiniportInitParameters* parameter of *MiniportInitializeEx*.

Return Status Codes

NDIS handles the OID query request of OID_SRIOV_PF_LUID request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_SRIOV_PF_LUID request, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The miniport driver must set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

MiniportInitializeEx

NDIS_OID_REQUEST

NDIS_SRIOV_PF_LUID_INFO

OID_SRIOV_PROBED_BARS

Article • 02/18/2023

NDIS issues an object identifier (OID) query request of OID_SRIOV_PROBED_BARS to obtain the values of a network adapter's PCI Express (PCIe) Base Address Registers (BARs). This function returns the BAR values that were reported by the network adapter following a query performed by the PCI bus driver. This query determines the memory or I/O address space that is required by the network adapter.

NDIS issues OID query requests of OID_SRIOV_PROBED_BARS to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID query request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer is formatted to contain the following:

- An NDIS_SRIOV_PROBED_BARS_INFO structure that contains the parameters for a read operation on the PCI BARs of a network adapter.

- An array of ULONG values for each BAR of the PCIe network adapter. The maximum number of elements within this array is PCI_TYPE0_ADDRESSES.

Remarks

The PCI bus driver, which runs in the management operating system of the Hyper-V parent partition, queries the memory or I/O address space requirements of each PCI Base Address Register (BAR) of the network adapter. The PCI bus driver performs this query when it first detects the adapter on the bus.

Through this PCI BAR query, the PCI bus driver determines the following:

- Whether a PCI BAR is supported by the network adapter.

- If a BAR is supported, how much memory or I/O address space is required for the BAR.

The virtual PCI (VPCI) bus driver runs in the guest operating system of a Hyper-V child partition. When a PCI Express (PCIe) Virtual Function (VF) is attached to the child partition, the VPCI bus driver will expose a virtual network adapter for the VF (*VF network adapter*). Before it does this, the VPCI bus driver must perform a PCI BAR query to determine the required memory or address space that is required by the VF network adapter.

Because access to the PCI configuration space is a privileged operation, it can only be performed by components that run in the management operating system of a Hyper-V parent partition. When the VPCI bus driver queries the PCI BARs, NDIS issues an OID query request of OID_SRIOV_PROBED_BARS to the PF miniport driver. The results returned by this OID query request are forwarded to the VPCI bus driver so that it can determine how much memory address space would be needed by the VF network adapter.

Note OID requests of OID_SRIOV_PROBED_BARS can only be issued by NDIS. The OID request must not be issued by overlying drivers, such as protocol of filter drivers.

The OID_SRIOV_PROBED_BARS query request contains an NDIS_SRIOV_PROBED_BARS_INFO structure. When the PF miniport driver handles this OID, the driver must return the PCI BAR values within the array referenced by the **BaseRegisterValuesOffset** member of the **NDIS_SRIOV_PROBED_BARS_INFO** structure. For each offset within the array, the PF miniport driver must set the array element to the ULONG value of the BAR at the same offset within the physical adapter's PCI configuration space.

Each BAR value returned by the driver must be the same value that would follow a PCI BAR query as performed by the PCI driver that runs in the management operating system. The PF miniport driver can call NdisMQueryProbedBars to determine this information.

For more information about the BARs of a PCI device, see the *PCI Local Bus Specification*.

For more information on how to query PCI BAR registers for a VF, see the Querying the PCI Base Address Registers of a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the query request of OID_SRIOV_PROBED_BARS:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.

Status Code	Description
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_PROBED_BARS_INFO structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer is less than (sizeof(NDIS_SRIOV_PROBED_BARS_INFO) + PCI_TYPE0_ADDRESSES). The PF miniport driver must set the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

NDIS_SRIOV_PROBED_BARS_INFO

NdisMQueryProbedBars

OID_SRIOV_READ_VF_CONFIG_BLOCK

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_SRIOV_READ_VF_CONFIG_BLOCK to read data from a specified PCI Express (PCIe) Virtual Function (VF) configuration block.

Overlying drivers issue this OID method request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure that contains the offset, in units of bytes, from the beginning of this structure to a location within the buffer that contains the data that is read from the VF configuration block.

- Additional buffer space for the data to be read from the specified VF configuration block.

Remarks

A VF configuration block is used for backchannel communication between the PF and VF miniport drivers. The IHV can define one or more VF configuration blocks for the miniport drivers. Each VF configuration block has an IHV-defined format, length, and block ID.

Note Data from each VF configuration block is used only by the PF and VF miniport drivers.

Before it issues the OID method request of OID_SRIOV_READ_VF_CONFIG_BLOCK, the overlying driver must set the members of NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure in the following way:

- Set the **VFId** member to the identifier of the VF from which the information is to be read.

- Set the **BlockId** member to the identifier of the VF configuration block from which the information is to be read.

- Set the **Length** member to the number of bytes to read from the configuration block.

- Set the **BufferOffset** member to the offset within the buffer (referenced by **InformationBuffer** member) that will contain the data that is read from the specified VF configuration block. This offset is specified in units of bytes from the beginning of the NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure.

When it handles the OID method request of OID_SRIOV_READ_VF_CONFIG_BLOCK, the PF miniport driver must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The PF miniport driver must verify that the **BlockId** member of the NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure specifies a valid VF configuration block. If not, the driver must fail the OID request.

For more information about backchannel communication within the single root I/O virtualization (SR-IOV) interface, see SR-IOV PF/VF Backchannel Communication.

Return Status Codes

The PF miniport driver returns one of the following status codes for the method request of OID_SRIOV_READ_VF_CONFIG_BLOCK.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS structure have invalid values.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_SRIOV_READ_VF_CONFIG_BLOCK_PARAMETERS

OID_NIC_SWITCH_ALLOCATE_VF

OID_SRIOV_READ_VF_CONFIG_SPACE

OID_SRIOV_READ_VF_CONFIG_SPACE

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_SRIOV_READ_VF_CONFIG_SPACE to read data from the PCI Express (PCIe) configuration space for a specified PCIe Virtual Function (VF) on the network adapter.

After a successful return from this OID method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS structure that contains the parameters for a read operation of the PCI configuration space of a VF.
- Additional buffer space for the data to be read from the PCI configuration space.

Remarks

The VF miniport driver runs in the guest operating system of a Hyper-V child partition. Because of this, the VF miniport driver cannot directly access hardware resources, such as the VF's PCI configuration space. Only the miniport driver for the PCIe Physical Function (PF) can access the PCI configuration space for a VF. The PF miniport driver runs in the management operating system of a Hyper-V parent partition and has privileged access to the VF resources.

In order to read the VF PCI configuration space, overlying drivers that run in the management operating system issue the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE to the PF miniport driver. This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

For example, the virtualization stack that runs in the management operating system issues the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE when the VF miniport driver calls NdisMGetBusData to read from its VF PCI configuration space.

When it handles the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE, the PF miniport driver must follow these guidelines:

- The miniport driver must verify that the VF, specified by the **VFId** member of the NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS structure, has resources that have been previously allocated. The miniport driver allocates resources for a VF through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The miniport driver must verify that the buffer (referenced by the **InformationBuffer** member of the NDIS_OID_REQUEST structure) is large enough to return the requested PCIe configuration space data. If this is not true, the driver must fail the OID request.

- The miniport driver typically calls NdisMGetVirtualFunctionBusData to query the requested PCIe configuration space. However, the miniport driver can also return PCIe configuration space data for the VF that the driver has cached from previous read or write operations of the PCIe configuration space.

  Note If an independent hardware vendor (IHV) provides a virtual bus driver (VBD) as part of its SR-IOV driver package, its miniport driver must not call NdisMGetVirtualFunctionBusData. Instead, the driver must interface with the VBD through a private communication channel, and request that the VBD call *ReadVfConfigBlock*. This function is exposed from the GUID_VPCI_INTERFACE_STANDARD interface that is supported by the underlying virtual PCI (VPCI) bus driver.

If the PF miniport driver can successfully complete the OID request, the driver must copy the requested PCI configuration space data to the buffer referenced by the **InformationBuffer** member of the NDIS_OID_REQUEST structure. The driver copies the data to the buffer at the offset specified by **BufferOffset** member of NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS structure.

For more information, see Querying the PCI Configuration Data of a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.

Status Code	Description
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The miniport driver must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SRIOV_RESET_VF

Article • 02/18/2023

Overlying drivers issue an object identifier (OID) set request of OID_SRIOV_RESET_VF to reset a specified PCI Express (PCIe) Virtual Function (VF) on a network adapter that supports single root I/O virtualization. Overlying drivers issue this OID set request to the miniport driver of the PCI Express (PCIe) Physical Function (PF) of the network adapter.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SRIOV_RESET_VF_PARAMETERS** structure. The overlying driver specifies the identifier of the VF to be reset through the **VFId** member of this structure.

Remarks

A VF can be reset through a PCI Express (PCIe) Function Level Reset (FLR). Because the FLR request is a privileged operation, it can only be performed by the PF miniport driver that runs in the management operating system of a Hyper-V parent partition. Overlying drivers that run in the management operating system are notified of the FLR request and issue the OID set request of OID_SRIOV_RESET_VF to the PF miniport driver.

When it handles this OID request, the PF miniport driver must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_RESET_VF_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The reset operation must only affect the specified VF. The operation must not affect other VFs or the PF on the same network adapter.

For more information, see Resetting a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the set request of OID_SRIOV_RESET_VF.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	Description
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_RESET_VF_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The PF miniport driver must set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SRIOV_SET_VF_POWER_STATE

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_SRIOV_SET_VF_POWER_STATE to change the power state of a specified PCI Express (PCIe) Virtual Function (VF) on the network adapter. Since changing the power state is a privileged operation, overlying drivers issue this OID set request to the miniport driver of the PCIe Physical Function (PF) on the network adapter. The PF miniport driver then sets the specified power state on the VF.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS** structure.

Remarks

When the PF miniport driver is issued this OID set request, it must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If the specified VF is not in an allocated state, the driver must fail the OID request.
- The power state operation must only affect the specified VF. The operation must not affect other VFs or the PF on the same network adapter.

For more information, see Setting the Power State of a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID set request of OID_SRIOV_SET_VF_POWER_STATE.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.

Status Code	Description
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. The PF miniport driver must set the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

NDIS_OID_REQUEST

NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS

OID_NIC_SWITCH_ALLOCATE_VF

OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK

Article • 02/18/2023

NDIS issues an object identifier (OID) method request of OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK to notify the miniport driver of a PCI Express (PCIe) Virtual Function (VF) that data within one or more configuration blocks has changed. NDIS issues this OID when the miniport driver for a PCIe Physical Function (PF) calls NdisMInvalidateConfigBlock.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SRIOV_VF_INVALIDATE_CONFIG_BLOCK_INFO structure. This structure specifies one or more Virtual Function (VF) configuration blocks whose data has been changed (*invalidated*) by the PF miniport driver.

Remarks

A VF configuration block is used for backchannel communication between the PF and VF miniport drivers. The IHV can define one or more VF configuration blocks for the device. Each VF configuration block has an IHV-defined format, length, and block ID.

Note Data from each VF configuration block is used only by the PF and VF miniport drivers.

VF configuration data is exchanged between the following drivers:

- The VF driver, which runs in the guest operating system. This operating system runs within a Hyper-V child partition.
- The PF driver, which runs in the management operating system. This operating system runs within the Hyper-V parent partition.

In order to handle notifications of invalid VF configuration data, NDIS and the miniport drivers perform the following steps:

1. In the guest operating system, NDIS issues an I/O control request of IOCTL_VPCI_INVALIDATE_BLOCK request. When this IOCTL is completed, NDIS is notified that VF configuration data has changed.
2. In the management operating system, the following steps occur:

a. The PF miniport driver calls the NdisMInvalidateConfigBlock function to notify NDIS that VF configuration data has changed and is no longer valid. The driver sets the *BlockMask* parameter to a ULONGLONG bitmask that specifies which VF configuration blocks have changed. Each bit in the bitmask corresponds to a VF configuration block. If the bit is set to one, the data in the corresponding VF configuration block has changed.

b. NDIS signals the virtualization stack, which runs in the management operating system, about the change to VF configuration block data. The virtualization stack caches the *BlockMask* parameter data.

   Note Each time that the PF miniport driver calls NdisMInvalidateConfigBlock, the virtualization stack ORs the *BlockMask* parameter data with the current value in its cache.

c. The virtualization stack notifies the virtual PCI (VPCI) driver, which runs in the guest operating system, about the invalidation of VF configuration data. The virtualization stack sends the cached *BlockMask* parameter data to the VPCI driver.

3. In the Guest operating system, the following steps occur:

   a. The VPCI driver saves the cached *BlockMask* parameter data in the **BlockMask** member of the VPCI_INVALIDATE_BLOCK_OUTPUT structure that is associated with the IOCTL_VPCI_INVALIDATE_BLOCK request.

   b. The VPCI driver successfully completes the IOCTL_VPCI_INVALIDATE_BLOCK request. When this happens, NDIS issues an OID method request of OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK to the VF miniport driver. An NDIS_SRIOV_VF_INVALIDATE_CONFIG_BLOCK_INFO is passed along in the OID request. This structure contains the cached *BlockMask* parameter data.

      NDIS also issues another IOCTL_VPCI_INVALIDATE_BLOCK request to handle successive notifications of changes to VF configuration data.

   c. When the VF driver handles the OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK request, it reads data from the specified VF configuration blocks.

For more information about backchannel communication within the single root I/O virtualization (SR-IOV) interface, see SR-IOV PF/VF Backchannel Communication.

Return Status Codes

The miniport driver returns one of the following status codes for the OID method request of OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_VF_INVALIDATE_CONFIG_BLOCK_INFO structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the size of the NDIS_SRIOV_VF_INVALIDATE_CONFIG_BLOCK_INFO structure.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SRIOV_VF_SERIAL_NUMBER

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_SRIOV_VF_SERIAL_NUMBER to determine the serial number of the PCI Express (PCIe) Virtual Function (VF) network adapter. This virtual network adapter is exposed in the guest operating system of a Hyper-V child partition to which the VF is attached.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SRIOV_VF_SERIAL_NUMBER_INFO** structure.

Remarks

The overlying driver uses the serial number to map the VF network adapter to an instance of a VF on the physical network adapter. The serial number is generated by the virtualization stack before resources for the VF are allocated through an OID set request of OID_NIC_SWITCH_ALLOCATE_VF.

Return Status Codes

NDIS handles the OID query request of the OID_SRIOV_VF_SERIAL_NUMBER request for miniport drivers. The drivers will not be issued this OID request.

When NDIS handles the OID_SRIOV_VF_SERIAL_NUMBER request, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

NDIS_SRIOV_VF_SERIAL_NUMBER_INFO

OID_NIC_SWITCH_ALLOCATE_VF

OID_SRIOV_VF_VENDOR_DEVICE_ID

Article • 02/18/2023

An overlying driver issues an object identifier (OID) method request of OID_SRIOV_VF_VENDOR_DEVICE_ID to query the PCI Express (PCIe) device identifier (DeviceID) and vendor identifier (VendorID) for a PCI Express (PCIe) Virtual Function (VF) network adapter. This virtual network adapter is exposed in the Hyper-V child partition that is attached to the VF.

Overlying drivers issue this OID method request to the miniport driver of the PCI Express (PCIe) Physical Function (PF) of the network adapter. This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SRIOV_VF_VENDOR_DEVICE_ID_INFO structure.

Remarks

Before it issues this OID method request, the overlying driver must initialize an NDIS_SRIOV_VF_VENDOR_DEVICE_ID_INFO structure and must set the **VFId** member to the identifier of the VF from which the information is to be read.

When it handles this OID request, the PF miniport driver must verify that the specified VF has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

For more information, see Querying the PCI Vendor and Device Identifiers for a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID method request of OID_SRIOV_VF_VENDOR_DEVICE_ID.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	Description
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the NDIS_SRIOV_VF_VENDOR_DEVICE_ID_INFO structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_OID_REQUEST

NDIS_SRIOV_VF_VENDOR_DEVICE_ID_INFO

OID_NIC_SWITCH_ALLOCATE_VF

OID_SRIOV_WRITE_VF_CONFIG_BLOCK

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_SRIOV_WRITE_VF_CONFIG_BLOCK to write data to a PCI Express (PCIe) Virtual Function (VF) configuration block.

Overlying drivers issue this OID set request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS structure that contains the offset, in units of bytes, from the beginning of this structure to a location within the buffer that contains the data that is written to the VF configuration block.
- Additional buffer space for the data to be written to the specified VF configuration block.

Remarks

A VF configuration block is used for backchannel communication between the PF and VF miniport drivers. The IHV can define one or more VF configuration blocks for the miniport drivers. Each VF configuration block has an IHV-defined format, length, and block ID.

Note Data from each VF configuration block is used only by the PF and VF miniport drivers.

Before it issues the OID set request of OID_SRIOV_WRITE_VF_CONFIG_BLOCK, the overlying driver must set the members of NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS structure in the following way:

- Set the **VFId** member to the identifier of the VF for which the information is to be written.
- Set the **BlockId** member to the identifier of the configuration block from which the information is to be written.

- Set the **Length** member to the number of bytes to write to the VF configuration block.
- Set the **BufferOffset** member to the offset within the buffer (referenced by **InformationBuffer** member) that contains the data that is to be written from the specified VF configuration block. This offset is specified in units of bytes from the beginning of the **NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS** structure.

When it handles the OID set request of OID_SRIOV_WRITE_VF_CONFIG_BLOCK, the PF miniport driver must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.
- The PF miniport driver must verify that the **BlockId** member of the **NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS** structure specifies a valid VF configuration block. If not, the driver must fail the OID request.

For more information about backchannel communication within the single root I/O virtualization (SR-IOV) interface, see SR-IOV PF/VF Backchannel Communication.

Return Status Codes

The miniport driver returns one of the following status codes for the OID set request of OID_SRIOV_WRITE_VF_CONFIG_BLOCK:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the **NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS** structure have invalid values.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_SRIOV_WRITE_VF_CONFIG_BLOCK_PARAMETERS

OID_NIC_SWITCH_ALLOCATE_VF

OID_SRIOV_READ_VF_CONFIG_SPACE

OID_SRIOV_WRITE_VF_CONFIG_SPACE

Article • 02/18/2023

An overlying driver issues an object identifier (OID) set request of OID_SRIOV_WRITE_VF_CONFIG_SPACE to write data to the PCI Express (PCIe) configuration space for a specified PCIe Virtual Function (VF) on the network adapter.

Overlying drivers issue this OID set request to the miniport driver for the network adapter's PCIe Physical Function (PF). This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS structure that contains the parameters for a write operation of the PCI configuration space of a VF.
- Additional buffer space that contains the data to be written to the PCI configuration space.

Remarks

The VF miniport driver runs in the guest operating system of a Hyper-V child partition. Because of this, the VF miniport driver cannot directly access hardware resources, such as the VF's PCI configuration space. Only the PF miniport driver, which runs in the management operating system of a Hyper-V parent partition, can access the PCI configuration space for a VF.

The overlying driver, such as the virtualization stack, issues the OID set request of OID_SRIOV_WRITE_VF_CONFIG_SPACE when the VF miniport driver calls NdisMSetBusData to write to its PCI configuration space.

When it handles the OID method request of OID_SRIOV_WRITE_VF_CONFIG_SPACE, the PF miniport driver must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The PF miniport driver calls **NdisMSetVirtualFunctionBusData** to write to the requested PCI configuration space. However, the PF miniport driver can also return PCI configuration space data for the VF that the driver has cached from previous read or write operations of the PCI configuration space.

  Note If an independent hardware vendor (IHV) provides a virtual bus driver (VBD) as part of its SR-IOV driver package, its PF miniport driver must not call **NdisMSetVirtualFunctionBusData**. Instead, the driver must interface with the VBD through a private communication channel, and request that the VBD call *SetVirtualFunctionData*. This function is exposed from the GUID_VPCI_INTERFACE_STANDARD interface that is supported by the underlying virtual PCI (VPCI) bus driver.

If the PF miniport driver can successfully complete the OID request, the driver must copy the requested PCI configuration space data to the buffer referenced by the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure. The driver copies the data to the buffer at the offset specified by **BufferOffset** member of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure.

For more information, see Setting the PCI Configuration Data of a Virtual Function.

Return Status Codes

The PF miniport driver returns one of the following status codes for the OID set request of OID_SRIOV_WRITE_VF_CONFIG_SPACE.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The PF miniport driver either does not support the single root I/O virtualization (SR-IOV) interface or is not enabled to use the interface.
NDIS_STATUS_INVALID_PARAMETER	One or more of the members of the **NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS** structure have invalid values.
NDIS_STATUS_INVALID_LENGTH	The information buffer was too short. NDIS sets the **DATA.SET_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.

Status Code	Description
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_FEATURE_STATUS_QUERY

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) method request of OID_SWITCH_FEATURE_STATUS_QUERY to obtain custom status information from an extension about the extensible switch. This information is known as *feature status* information. The format of this information is defined by the independent software vendor (ISV).

After a successful return from this OID method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_FEATURE_STATUS_PARAMETERS structure that specifies the parameters for the type of feature status information to be returned.
- An NDIS_SWITCH_FEATURE_STATUS_CUSTOM structure that contains the feature status information for the extensible switch.

Remarks

For guidelines on how to handle an OID set request of OID_SWITCH_FEATURE_STATUS_QUERY, see Managing Custom Switch Feature Status Information.

Return Status Codes

The extension returns one of the following status codes for the OID method request of OID_SWITCH_FEATURE_STATUS_QUERY.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the feature status information as well as the NDIS_SWITCH_FEATURE_STATUS_CUSTOM and NDIS_SWITCH_FEATURE_STATUS_PARAMETERS structures. The underlying miniport edge of the extensible switch sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_SWITCH_FEATURE_STATUS_CUSTOM

NDIS_SWITCH_FEATURE_STATUS_PARAMETERS

OID_SWITCH_NIC_ARRAY

Article • 02/18/2023

A Hyper-V extensible switch extension issues an object identifier (OID) query request of OID_SWITCH_NIC_ARRAY to obtain an array. Each element in the array specifies the configuration parameters of a virtual network adapter that is associated with an extensible switch port.

If the OID query request is completed successfully, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_NIC_ARRAY structure that defines the number of elements in the array. This structure also specifies the offset to the first element in the array.
- An array of NDIS_SWITCH_NIC_PARAMETERS structures. Each of these structures contains information about a network adapter that is connected to an extensible switch port.

  Note If no network adapters are connected to extensible switch ports, the underlying miniport edge of the extensible switch sets the **NumElements** member of the NDIS_SWITCH_NIC_ARRAY structure to zero. In this case, no NDIS_SWITCH_NIC_PARAMETERS structures are returned.

Remarks

The OID_SWITCH_NIC_ARRAY OID must only be issued when the Hyper-V extensible switch has completed activation. Please see Querying the Hyper-V Extensible Switch Configuration for more details.

When the extension processes the returned NDIS_SWITCH_NIC_PARAMETERS structure, it must not assume that the various string members of the NDIS_SWITCH_PORT_PARAMETERS structure, such as **NicFriendlyName**, are NULL-terminated. The data types for these string members are type-defined by the IF_COUNTED_STRING structure. The driver must determine the string length from the value of the **Length** member of this structure.

Note If the string is null-terminated, the **Length** member must not include the terminating null character.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_ARRAY and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the NDIS_SWITCH_NIC_ARRAY and its array of NDIS_SWITCH_NIC_PARAMETERS elements. The underlying miniport edge of the extensible switch sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_SWITCH_NIC_PARAMETERS

Querying the Hyper-V Extensible Switch Configuration

OID_SWITCH_NIC_CONNECT

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_CONNECT to notify underlying extensible switch extensions that a network connection between an extensible switch port and a network adapter is completely established. The protocol edge previously notified extensions that this connection is being established when it issued an OID set request of OID_SWITCH_NIC_CREATE.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_PARAMETERS** structure.

Remarks

The **PortId** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the extensible switch port for which the connect notification is being made. The extensible switch extension can obtain the parameter information for this port and other extensible switch ports in the following ways:

- By issuing OID query requests of OID_SWITCH_PORT_ARRAY. The extension issues this OID on *FilterAttach* only when OID_SWITCH_PARAMETERS returns an **NDIS_SWITCH_PARAMETERS** structure with **IsActive** set to TRUE. If **IsActive** is FALSE, the extension issues the OID when the **NetEventSwitchActivate** **NET_PNP_EVENT** is issued by the extension miniport adapter.

- By inspecting the various OID sets requests of OID_SWITCH_PORT_CREATE and OID_SWITCH_PORT_DELETE.

The **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the index of a network adapter for which the connection notification is being made. The network adapter with the specified **Index** value is connected to the extensible switch port specified by the **PortId** member. For more information on these index values, see Network Adapter Index Values.

When it receives the OID set request of OID_SWITCH_NIC_CONNECT, the extension must follow these guidelines:

- When the OID_SWITCH_NIC_CONNECT request completes with NDIS_STATUS_SUCCESS, the network connection and extensible switch port are fully operational. The extension can generate or forward packet traffic to the port's network connection. The extension can also issue extensible switch OIDs or status indications that use the port as the source port. The extension can also call *ReferenceSwitchPort* to increment the extensible switch reference counter for the port.

- The extension must not modify the **NDIS_SWITCH_NIC_PARAMETERS** structure that is associated with the OID request.

- The extension must always call **NdisFOidRequest** to forward this OID request to underlying extensions. The extension must not complete the OID request itself.

- The extensible switch external network adapter can bind to one or more underlying physical adapters. For every physical network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_CONNECT. Each OID set request specifies a different network adapter connection index value. For more information on these values, see Network Adapter Index Values.

  The extension must maintain the connection state for each underlying physical adapter that is bound to the external network adapter. For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

Note The extension must not issue its own OID set requests of OID_SWITCH_NIC_CONNECT.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID set request of OID_SWITCH_NIC_CONNECT and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

Header	Ntddndis.h (include Ndis.h)

NdisFOidRequest

OID_SWITCH_NIC_CREATE

OID_SWITCH_PORT_ARRAY

ReferenceSwitchPort

OID_SWITCH_NIC_CREATE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_CREATE to notify underlying extensible switch extensions that a new connection is being established between an extensible switch port and an external or virtual network adapter. After the connection is fully established, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_PARAMETERS** structure.

Remarks

The **PortId** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the extensible switch port for which the creation notification is being made. The extensible switch extension can obtain the parameter information for this and other ports on the extensible switch by issuing OID query requests of OID_SWITCH_PORT_ARRAY.

The **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the index of a network adapter for which the creation notification is being made. The network adapter with the specified **Index** value is connected to the extensible switch port specified by the **PortId** member. For more information on these index values, see Network Adapter Index Values.

When it receives the OID set request of OID_SWITCH_NIC_CREATE, the extension must follow these guidelines:

- The extension must not modify the **NDIS_SWITCH_NIC_PARAMETERS** structure that is associated with the OID request.

- The OID_SWITCH_NIC_CREATE request only notifies the extension that a new extensible switch connection is being brought up and that packet traffic may soon begin to occur over the specified port. However, the extension cannot use the port until the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT. Until that OID is issued, the extension must not do the following:

  - Generate any packet traffic to the network adapter connection on the extensible switch port for which the OID_SWITCH_NIC_CREATE OID request was issued.

  - Forward or originate OID requests of OID_SWITCH_NIC_REQUEST to an underlying network adapter for which the OID_SWITCH_NIC_CREATE OID request was issued.
  - Forward or originate NDIS status indications of **NDIS_STATUS_SWITCH_NIC_STATUS** from an underlying network adapter for which the OID_SWITCH_NIC_CREATE OID request was issued.
  - Call *ReferenceSwitchNic* to increment the extensible switch reference counter for the specified network adapter connection on the extensible switch port.

  Note The extension may intercept send or receive packets for the specified port between the OID requests of OID_SWITCH_NIC_CREATE and OID_SWITCH_NIC_CONNECT. In this case, the extension should forward the send or receive packet requests instead of canceling them.

- The extension can veto the creation notification by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot satisfy its configured policies on the specified port, the extension should veto the creation notification.

  If the extension returns other NDIS_STATUS_*Xxx* status codes, the creation notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

  If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

  Note The extension can only veto the OID request if the **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies a network adapter index value of zero.

- If the extension does not veto the creation notification, it must call **NdisFOidRequest** to forward this OID request to underlying extensions in the extensible switch driver stack.

  Note The extension should monitor the completion status of this OID request. The extension does this to detect whether underlying extensions in the extensible switch driver stack have vetoed the creation notification.

- If the extension calls **NdisFOidRequest** to forward this OID request, the extension will not immediately receive any packet traffic to or from the extensible switch port. In addition, the extension cannot immediately inject send or receive traffic for the extensible switch port.
- The extension can only forward packet traffic to the extensible switch port after the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT.

  Note In some situations, packet traffic may be forwarded by the extensible switch to the port before an OID set request of OID_SWITCH_NIC_CONNECT is issued.
- The extensible switch external network adapter can bind to one or more underlying physical adapters. For every physical network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_CREATE. Each OID set request specifies a different network adapter connection index value. For more information on these index values, see Network Adapter Index Values.

  The extension must maintain the connection state for each underlying physical adapter. For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Note The extension must not issue its own OID set requests of OID_SWITCH_NIC_CREATE.

Return Status Codes

If the extension completes the OID set request of OID_SWITCH_NIC_CREATE, it returns one of the following status codes.

Status Code	**Description**
NDIS_STATUS_DATA_NOT_ACCEPTED	The extension vetoed the creation notification.
NDIS_STATUS_RESOURCES	The extension vetoed the creation notification due to a low resource condition.
NDIS_STATUS_*Xxx*	The extension vetoed the creation notification for other reasons.

Note If the extension completes the OID set request, it must not return NDIS_STATUS_SUCCESS.

If the extension does not complete the OID set request of OID_SWITCH_NIC_CREATE, the request is completed by the underlying miniport edge of the extensible switch. The underlying miniport edge returns the following status code for this OID set request:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SWITCH_NIC_CONNECT

OID_SWITCH_PORT_ARRAY

ReferenceSwitchPort

OID_SWITCH_NIC_DELETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_DELETE to the extensible switch driver stack. This OID request notifies underlying extensible switch extensions about the deletion of a connection between an extensible switch port and a network adapter. The protocol edge of the extensible switch previously notified extensions that this connection is being deleted when it issued an OID set request of OID_SWITCH_NIC_DISCONNECT.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_PARAMETERS** structure.

Remarks

The **PortId** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the port for which the deletion notification is being made. The extensible switch extension can obtain the parameter information for this and other ports on the extensible switch by issuing OID query requests of OID_SWITCH_PORT_ARRAY.

The **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the index of a network adapter for which the deletion notification is being made. The network adapter with the specified **Index** value is connected to the extensible switch port specified by the **PortId** member. For more information on these index values, see Network Adapter Index Values.

Before the protocol edge of the extensible switch issues the OID_SWITCH_NIC_DELETE request, it guarantees that all pending send or receive packet requests for the specified network adapter connection have been completed. The protocol edge also guarantees that all pending OID requests for the adapter connection have been completed, and the extensible switch reference counters for the adapter connection have a zero value.

Note If the extension had incremented an extensible switch reference counter for the network adapter by calling *ReferenceSwitchNic*, the OID_SWITCH_NIC_DELETE request is not issued while the reference counter is nonzero. The extension decrements the extensible switch reference counter by calling *DereferenceSwitchNic*.

The extension must follow these guidelines for handling OID set requests of OID_SWITCH_NIC_DELETE:

- The extension must not modify the **NDIS_SWITCH_NIC_PARAMETERS** structure that is associated with the OID request.

- The extension must always forward this OID set request to underlying extensions. The extension must not complete the request.

- The extension must not issue its own OID set requests of OID_SWITCH_NIC_DELETE.

- The extensible switch external network adapter can bind to one or more underlying physical adapters. For every physical network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_DELETE. Each OID set request specifies a different network adapter connection index value. For more information on these index values, see Network Adapter Index Values.

  The extension must maintain the connection state for each underlying physical adapter. For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_DELETE and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_NIC_DISCONNECT

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_DISCONNECT to notify underlying extensible switch extensions that a connection between an extensible switch port and a network adapter is being torn down. After the connection is completely torn down, the protocol edge of the extensible switch will issue an OID set request of OID_SWITCH_NIC_DELETE.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_PARAMETERS** structure.

Remarks

The **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the index of a network adapter for which the disconnect notification is being made. The network adapter with the specified **Index** value is connected to the extensible switch port specified by the **PortId** member. For more information on these index values, see Network Adapter Index Values.

The extension must follow these guidelines when it handles OID set requests of OID_SWITCH_NIC_DISCONNECT:

- The extension must not modify the **NDIS_SWITCH_NIC_PARAMETERS** structure that is associated with the OID request.

- The OID_SWITCH_NIC_DISCONNECT request only notifies the extension that the extensible switch connection is being torn down between the specified network adapter and extensible switch port. After the extension handles this OID request, it must not do the following:

  - Generate any packet traffic to the network adapter connection on the extensible switch port for which the OID_SWITCH_NIC_DISCONNECT OID request was issued.

  - Call *ReferenceSwitchNic* to increment the extensible switch reference counter for the specified network adapter connection on the extensible switch port.

  - Forward or originate OID requests of OID_SWITCH_NIC_REQUEST to an underlying network adapter for which the OID_SWITCH_NIC_DISCONNECT OID request was issued.

Note If the extension called *ReferenceSwitchNic* to increment the extensible switch reference counter before the OID_SWITCH_NIC_DISCONNECT is issued, the extension can still forward or originate OID requests.

  - Forward or originate NDIS status indications of **NDIS_STATUS_SWITCH_NIC_STATUS** from an underlying network adapter for which the OID_SWITCH_NIC_DISCONNECT OID request was issued.

    Note If the extension called *ReferenceSwitchNic* to increment the extensible switch reference counter before the OID_SWITCH_NIC_DISCONNECT is issued, the extension can still forward or originate NDIS status indications.

    Note If the extension previously called *ReferenceSwitchNic* to increment the extensible switch reference counter, it does not need to synchronize its calls to originate or forward OID requests or NDIS status indications with its code that manages Hyper-V extensible switch OID requests. After the extension increments the reference counter, the extensible switch interface will not issue an OID set request of OID_SWITCH_NIC_DELETE.

- The extension must always forward this OID set request to underlying extensions. The extension must not complete the request.

- The extensible switch external network adapter can bind to one or more underlying physical adapters. For every physical network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_DISCONNECT. Each OID set request specifies a different network adapter connection index value. For more information on these index values, see Network Adapter Index Values.

  The extension must maintain the connection state for each underlying physical adapter. For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

Note The extension must not issue its own OID set requests of OID_SWITCH_NIC_DISCONNECT.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_DISCONNECT and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_NIC_REQUEST

Article • 02/18/2023

An object identifier (OID) method request of OID_SWITCH_NIC_REQUEST is used to encapsulate and forward OID requests to the Hyper-V extensible switch external network adapter. This allows the encapsulated OID request to be delivered to the driver for the underlying physical network adapter that is bound to the external network adapter.

This OID request is also used to encapsulate OID requests that were issued to other network adapters that are connected to extensible switch ports. In this case, the encapsulated OID request is forwarded through the extensible switch driver stack for inspection by extensions.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_NIC_OID_REQUEST structure. This structure specifies the forwarding information for the OID request. This structure also contains a pointer to the original **NDIS_OID_REQUEST** structure of the OID request that is being forwarded.

Remarks

When OID requests arrive at the Hyper-V extensible switch interface, it encapsulates them in order to forward them down the extensible switch control path. These OID requests include the following:

- Hardware offload OID requests, including requests for Internet Protocol security (IPsec), virtual machine queue (VMQ), and single root I/O virtualization (SR-IOV). These OID requests are issued by an overlying protocol or filter driver that runs in the management operating system of the Hyper-V parent partition.

  When these OID requests arrive at the extensible switch interface, the protocol edge of the extensible switch encapsulates the OID request within an NDIS_SWITCH_NIC_OID_REQUEST structure. The protocol edge sets the members of this structure in the following way:

  - The **DestinationPortId** and **DestinationNicIndex** members are set to the corresponding values for the external network adapter.

  - If the OID request was originated from a Hyper-V child partition, the **SourcePortId** and **SourceNicIndex** members are set to the corresponding values for the port and network adapter that are used by the partition. Otherwise, the **SourcePortId** and **SourceNicIndex** members are set to zero.

  Note The extension must retain the values of these members if it forwards or redirects the OID request.

  - The **OidRequest** member is set to a pointer to the **NDIS_OID_REQUEST** structure for the encapsulated OID request.

The protocol edge then issues the OID_SWITCH_NIC_REQUEST request to forward the encapsulated OID request down the extensible switch control path to the external network adapter.

An underlying forwarding extension can redirect encapsulated hardware offload OID requests to a physical network adapter that is bound to the external network adapter. For example, if the extension supports physical network adapters from an extensible switch team that are bound to the external network adapter, it can forward the OID_SWITCH_NIC_REQUEST request to a physical adapter in the load balancing failover (LBFO) team that supports the hardware offload. For more information on this procedure, see Managing Hardware Offload OID Requests to Physical Network Adapters.

For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

- Multicast OID requests, including OID_802_3_ADD_MULTICAST_ADDRESS and OID_802_3_DELETE_MULTICAST_ADDRESS. These OID requests are issued by overlying protocol and filter drivers that run in either the management operating system or the guest operating system of a Hyper-V child partition.

  When these OID requests arrive at the extensible switch interface, the protocol edge of the extensible switch encapsulates the OID request within an **NDIS_SWITCH_NIC_OID_REQUEST** structure. The protocol edge also sets the **SourcePortId** and **SourceNicIndex** members to the corresponding values for the port and network adapter from which the OID request originated. The protocol edge then issues the OID_SWITCH_NIC_REQUEST request to forward the encapsulated OID request down the extensible switch control path for inspection by underlying extensions.

  Note In this case, the protocol edge sets the **DestinationPortId** and **DestinationNicIndex** members to zero. This specifies that the encapsulated OID request is to be delivered to extensions in the control path.

Underlying forwarding extensions can inspect these encapsulated OID requests and retain the multicast address information that they specify. For example, the extension may need this information if it originates multicast packets that it forwards to an extensible switch port.

For more information, see Forwarding OID Requests from a Hyper-V Child Partition.

A forwarding extension can also issue an OID_SWITCH_NIC_REQUEST in order to forward encapsulated OID requests to a physical network adapter that is bound to the external network adapter. This allows the extension to originate its own OID request or redirect an existing OID request to a physical network adapter that is bound to the external network adapter. In order to do this, the extension must follow these steps:

1. The extension calls *ReferenceSwitchNic* to increment a reference counter for the index of the destination physical network adapter. This guarantees that the extensible switch interface will not delete the physical network adapter connection while its reference counter is nonzero.

   Note The extensible switch interface could disconnect the physical network adapter connection while its reference counter is nonzero. For more information, see Hyper-V Extensible Switch Port and Network Adapter States.

2. The extension encapsulates the OID request by initializing an **NDIS_SWITCH_NIC_OID_REQUEST** structure in the following way:

   - The **DestinationPortId** member must be set to the identifier of the extensible switch port to which the external network adapter is connected.

   - The **DestinationNicIndex** member must be set to the nonzero index value of the underlying physical network adapter.

   - If the extension is originating on behalf of a Hyper-V child partition, the **SourcePortId** and **SourceNicIndex** members are set to the corresponding values for the port and network adapter that are used by the partition. Otherwise, the **SourcePortId** and **SourceNicIndex** members are set to zero.

     For example, if the extension is managing hardware offload resources for a child partition, it must set the **SourcePortId** and **SourceNicIndex** members to specify which partition the encapsulated hardware offload OID request is for.

   - The **OidRequest** member must be set to a pointer to an initialized **NDIS_OID_REQUEST** structure for the encapsulated OID request.

3. The extension calls **NdisFOidRequest** to forward the OID request to the specified destination extensible switch port and network adapter.

4. When NDIS calls the *FilterOidRequestComplete* function, the extension calls *DereferenceSwitchNic* to clear the reference counter for the index of the destination physical network adapter.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_REQUEST and returns one of the following status codes.

Status Code	**Description**
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_*Xxx*	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_STATUS_INDICATION

NDIS_SWITCH_NIC_OID_REQUEST

OID_SWITCH_NIC_RESTORE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_RESTORE to notify the extensible switch extension about run-time data that can be restored for an extensible switch port and its network adapter connection.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_NIC_SAVE_STATE structure. This structure is allocated by the protocol edge of the extensible switch.

Remarks

When it receives the OID set request of OID_SWITCH_NIC_RESTORE, the extensible switch extension must first determine whether it owns the run-time data. The extension does this by comparing the value of the **ExtensionId** member of the NDIS_SWITCH_NIC_SAVE_STATE structure to the GUID value that the extension uses to identify itself.

If the extension owns the run-time data for an extensible switch port, it restores this data in the following way:

1. The extension copies the run-time data in the **SaveData** member to extension-allocated storage.

   Note The value of the **PortId** member of the NDIS_SWITCH_NIC_SAVE_STATE structure may be different from the **PortId** value at the time that the run-time data was saved. This can occur if run-time data was saved during a Live Migration from one host to another. However, the configuration of the extensible switch port is retained during the Live Migration. This enables the extension to restore the run-time data to the extensible switch port by using the new **PortId** value.

2. The extension completes the OID set request with NDIS_STATUS_SUCCESS.

If the extension does not own the specified run-time data, the extension calls NdisFOidRequest to forward this OID set request to underlying extensions in the extensible switch driver stack. In this case, the extension must not modify the NDIS_SWITCH_NIC_SAVE_STATE structure that is associated with the OID request.

If the OID_SWITCH_NIC_RESTORE set request is received by the miniport edge of the extensible switch, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that no extension owns the run-time data.

For more information about how to restore run-time data, see Restoring Hyper-V Extensible Switch Run-Time Data.

Note If the extension fails the OID set request, the extensible switch will fail the entire restore operation. As a result, the extension should avoid failing the OID request if it is possible. For example, if the extension cannot allocate the resource necessary to restore the run-time data, it should fail the OID request if it cannot function properly without restoring the run-time data. However, if the extension can recover from the failure condition, it should not fail the OID set request.

Return Status Codes

If the extension completes the OID set request of OID_SWITCH_NIC_RESTORE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_*Xxx*	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_NIC_RESTORE_COMPLETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_RESTORE_COMPLETE to notify Hyper-V extensible switch extensions about the completion of the operation to restore run-time data. Through this operation, the extension restores its run-time data for a port and its associated network adapter connection.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure. This structure is allocated by the protocol edge of the extensible switch.

Remarks

When it receives the OID set request of OID_SWITCH_NIC_RESTORE_COMPLETE, the extension must follow these guidelines:

- The extension must not modify the **NDIS_SWITCH_NIC_SAVE_STATE** structure that is associated with the OID request.
- The extension must call **NdisFOidRequest** to forward this OID set request to underlying extensions in the extensible switch driver stack. The extension must not fail the OID request.

OID set requests of OID_SWITCH_NIC_RESTORE_COMPLETE are ultimately handled by the underlying miniport edge of the extensible switch. After this OID method request has been received by the miniport edge, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that all extensions in the extensible switch driver stack have completed the save operation.

For more information on how to save run-time data for an extensible switch port, see Saving Hyper-V Extensible Switch Run-Time Data.

Return Status Codes

If the extension completes the OID set request of OID_SWITCH_NIC_RESTORE_COMPLETE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_OID_REQUEST

NDIS_SWITCH_NIC_SAVE_STATE

OID_SWITCH_NIC_SAVE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) method request of OID_SWITCH_NIC_SAVE during an operation to save run-time data for an extensible switch port and its network adapter connection. The extension returns this data so that run-time data can be saved and restored at a later time. After the run-time data is saved, it is restored through OID set requests of OID_SWITCH_NIC_RESTORE.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure. This structure is allocated by the protocol edge of the extensible switch.

Remarks

When it receives the OID method request of OID_SWITCH_NIC_SAVE, the extensible switch extension saves run-time data by doing the following:

- The extension saves the data within the **NDIS_SWITCH_NIC_SAVE_STATE** structure starting from *SaveDataOffset* bytes from the start of the structure.

- If the *SaveDataSize* provided is not large enough to hold the required save data, the extension sets the method structure's *BytesNeeded* field to NDIS_SIZEOF_NDIS_SWITCH_NIC_SAVE_STATE_REVISION_1 plus the amount of buffer necessary to hold the save data, and completes the OID with NDIS_STATUS_BUFFER_TOO_SHORT. The OID will be reissued with the required size.

- The extension populates the *ExtensionId* and *ExtensionFriendlyName* fields with its own identifier and name, and completes the OID method request with NDIS_STATUS_SUCCESS. This causes the protocol edge of the extensible switch to issue another OID method request to allow the extension to either return more save data, or allow other extensions down the stack to save their own data.

Note If the extension does not have run-time data to save, it must call **NdisFOidRequest** to forward this OID method request to underlying extensions in the extensible switch driver stack. For more information about this procedure, see Filtering OID Requests in an NDIS Filter Driver.

The Hyper-V extensible switch populates the *Header*, *PortId*, *NicIdex*, *SaveDataSize* and *SaveDataOffset* fields of the structure before issuing the OID. The extension cannot modify these fields.

OID method requests of OID_SWITCH_NIC_SAVE are ultimately handled by the underlying miniport edge of the extensible switch. After this OID method request has been received by the miniport edge of the extensible switch, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that all extensions in the extensible switch driver stack have been queried for run-time data. The protocol edge of the extensible switch then issues an OID set request of OID_SWITCH_NIC_SAVE_COMPLETE to complete the save operation.

For more information on how to save run-time data for an extensible switch port, see Saving Hyper-V Extensible Switch Run-Time Data.

Return Status Codes

The extensible switch extension returns one of the following status codes for the OID method request of OID_SWITCH_NIC_SAVE.

Status Code	Description
NDIS_STATUS_BUFFER_TOO_SHORT	The length of the information buffer is too small for the NDIS_SWITCH_NIC_SAVE_STATE and its associated run-time data The extensible switch extension must set the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_SUCCESS	The extension returns this status if it is returning run-time data to save.
NDIS_STATUS_*Xxx*	The request failed for other reasons.

The underlying miniport edge of the extensible switch returns the following status code for the OID method request of OID_SWITCH_NIC_SAVE.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SWITCH_NIC_SAVE_COMPLETE

OID_SWITCH_NIC_SAVE_COMPLETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_SAVE_COMPLETE to notify Hyper-V extensible switch extensions about the completion of the operation to save run-time data. Through this operation, the extension saves run-time data for a port and its associated network adapter connection.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure.

Remarks

When it receives the OID set request of OID_SWITCH_NIC_SAVE_COMPLETE, the extension must follow these guidelines:

- The extension must not modify the **NDIS_SWITCH_NIC_SAVE_STATE** structure that is associated with the OID request.
- The extension must call **NdisFOidRequest** to forward this OID set request to underlying extensions in the extensible switch driver stack. The extension must not fail the OID request.

OID set requests of OID_SWITCH_NIC_SAVE_COMPLETE are ultimately handled by the underlying miniport edge of the extensible switch. After this OID method request has been received by the miniport edge, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that all extensions in the extensible switch driver stack have completed the save operation.

For more information on how to save run-time data for an extensible switch port, see Saving Hyper-V Extensible Switch Run-Time Data.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_SAVE_COMPLETE and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

NDIS_OID_REQUEST

NDIS_SWITCH_NIC_SAVE_STATE

OID_SWITCH_NIC_UPDATED

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_UPDATED to the extensible switch driver stack. This OID request notifies underlying extensible switch extensions about the update of the parameters of a network adapter. The OID will only be issued for NICs that have already been connected, and have not yet begun the disconnect process. These run-time configuration changes can include **NicFriendlyName**, **NetCfgInstanceId**, **MTU**, **NumaNodeId**, **PermanentMacAddress**, **VMMacAddress**, **CurrentMacAddress**, and **VFAssigned**.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_NIC_PARAMETERS** structure.

Remarks

The **PortId** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the port for which the update notification is being made. The extensible switch extension can obtain the parameter information for this and other ports on the extensible switch by issuing OID query requests of OID_SWITCH_PORT_ARRAY.

The **Index** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the index of a network adapter for which the update notification is being made. The network adapter with the specified **Index** value is connected to the extensible switch port specified by the **PortId** member. For more information on these index values, see Network Adapter Index Values.

The extension must follow these guidelines for handling OID set requests of OID_SWITCH_NIC_UPDATED:

- The extension must not modify the **NDIS_SWITCH_NIC_PARAMETERS** structure that is associated with the OID request.
- The extension must always forward this OID set request to underlying extensions. The extension must not complete the request.
- The extension must not issue its own OID set requests of OID_SWITCH_NIC_UPDATED.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_NIC_UPDATED and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PARAMETERS

Article • 02/18/2023

A Hyper-V extensible switch extension issues an object identifier (OID) query request of OID_SWITCH_PARAMETERS to obtain the configuration data of the extensible switch.

If the OID query request completes successfully, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_PARAMETERS structure.

Remarks

When the extension processes the returned NDIS_SWITCH_PARAMETERS structure, it must not assume that the various string members of the **NDIS_SWITCH_PARAMETERS** structure, such as **SwitchName**, are null-terminated. The data types for these string members are type-defined by the IF_COUNTED_STRING structure. The extension must determine the string length from the value of the **Length** member of this structure.

Note If the string is null-terminated, the **Length** member must not include the terminating null character.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_PARAMETERS and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the OID_SWITCH_PARAMETERS structure for an OID query request. The underlying miniport edge of the extensible switch sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

NDIS_SWITCH_PARAMETERS

NdisFOidRequest

OID_SWITCH_PORT_ARRAY

Article • 02/18/2023

A Hyper-V extensible switch extension issues an object identifier (OID) query request of OID_SWITCH_PORT_ARRAY to obtain an array. Each element in the array specifies the configuration parameters for an extensible switch port.

If the OID query request completes successfully, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_ARRAY structure that defines the number of elements within the array.
- An array of NDIS_SWITCH_PORT_PARAMETERS structures. Each of these structures contains information about a port on the extensible switch.

  Note If no ports have been created on the extensible switch, the driver sets the **NumElements** member of the NDIS_SWITCH_PORT_ARRAY structure to zero and no NDIS_SWITCH_PORT_PARAMETERS structures are returned.

Remarks

The OID_SWITCH_PORT_ARRAY OID must only be issued when the Hyper-V extensible switch has completed activation. Please see Querying the Hyper-V Extensible Switch Configuration for more details.

When the extension handles the returned NDIS_SWITCH_PORT_PARAMETERS structure, it must not assume that the various string members of the **NDIS_SWITCH_PORT_PARAMETERS** structure, such as **PortName**, are null-terminated. The data types for these string members are type-defined by the IF_COUNTED_STRING structure. The driver must determine the string length from the value of the **Length** member of this structure.

Note If the string is null-terminated, the **Length** member must not include the terminating null character.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_PORT_ARRAY and returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the NDIS_SWITCH_PORT_ARRAY and its array of NDIS_SWITCH_PORT_PARAMETERS elements. The underlying miniport edge of the extensible switch sets the **DATA.QUERY_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

Querying the Hyper-V Extensible Switch Configuration

OID_SWITCH_PORT_CREATE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_CREATE to notify extensible switch extensions about the creation of an extensible switch port.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_PORT_PARAMETERS structure.

Remarks

The **PortId** member of the NDIS_SWITCH_PORT_PARAMETERS structure specifies the port for which the creation notification is being made.

The extensible switch extension must follow these guidelines for handling OID set requests of OID_SWITCH_PORT_CREATE:

- The extension must not modify the NDIS_SWITCH_PORT_PARAMETERS structure that is associated with the OID request.

- The extension can veto the creation notification by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its configured policies on the port, the driver should veto the creation notification.

  If the extension returns other NDIS_STATUS_*Xxx* error status codes, the creation notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

  If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

  For more information on port policies, see Managing Hyper-V Extensible Switch Policies.

- If the extension calls **NdisFOidRequest** to forward this OID set request, the extension should monitor the completion status of this OID request. The extension does this to detect whether underlying extensions in the extensible switch driver stack have vetoed the port creation notification.

- After the OID request is forwarded and completes successfully, the extension can issue OIDs requests for the port, such as OID_SWITCH_PORT_PROPERTY_ENUM, until an OID request of OID_SWITCH_PORT_TEARDOWN is issued. This OID request notifies the extension that the port will begin the deletion process from the extensible switch.

- Extensions cannot forward packets to the specified port in the **NDIS_SWITCH_PORT_PARAMETERS** structure until an OID set request of OID_SWITCH_NIC_CONNECT is issued and is completed successfully.

Note Extensions must not issue OID set requests of OID_SWITCH_PORT_CREATE.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

If the extension completes the OID set request of OID_SWITCH_PORT_CREATE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_DATA_NOT_ACCEPTED	The extension vetoed the creation notification.
NDIS_STATUS_RESOURCES	The extension vetoed the creation notification due to a low resource condition.
NDIS_STATUS_*Xxx*	The extension vetoed the creation notification for other reasons.

Note If the extension completes the OID set request, it must not return NDIS_STATUS_SUCCESS.

If the extension does not complete the OID set request of OID_SWITCH_PORT_CREATE, the request is completed by the underlying miniport edge of the extensible switch. The underlying miniport edge returns the following status code for this OID set request.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

NdisFOidRequest

OID_SWITCH_NIC_CONNECT

OID_SWITCH_PORT_ARRAY

OID_SWITCH_PORT_PROPERTY_ENUM

OID_SWITCH_PORT_DELETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_DELETE to notify extensible switch extensions about the deletion of an extensible switch port.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_PORT_PARAMETERS structure.

Remarks

The **PortId** member of the NDIS_SWITCH_PORT_PARAMETERS structure specifies the extensible switch port for which the delete notification is being made.

If a network adapter is connected to the specified port, the protocol edge of the extensible switch will delete the connection before it deletes the port. In this case, the protocol edge will follow these steps before it deletes the port:

- The protocol edge issues an OID set request of OID_SWITCH_NIC_DISCONNECT to notify the extension that the connection between a network adapter and the extensible switch port is being deleted.

- After all pending packets for the specified extensible switch port have been canceled or completed, the protocol edge issues an OID set request of OID_SWITCH_NIC_DELETE to notify the extension that the connection between a network adapter and the extensible switch port has been deleted.

  At this point, the protocol edge can start to delete the port.

The protocol edge of the extensible switch follows these steps when it deletes an extensible switch port:

1. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN. This OID request notifies underlying extensible switch extensions about the start of the deletion process for an extensible switch port.

2. The protocol edge issues an OID set request of OID_SWITCH_PORT_DELETE after all OID requests to the extensible switch port have completed.

   Note If the extension had previously called *ReferenceSwitchPort* to increment the port's reference counter, it must call *DereferenceSwitchPort* before the protocol edge issues the OID_SWITCH_NIC_DELETE request.

The extension must follow these guidelines for handling OID set requests of OID_SWITCH_PORT_DELETE:

- The extension must not modify the **NDIS_SWITCH_PORT_PARAMETERS** structure that is associated with the OID request.

- The extension must always forward this OID set request to underlying extensions. The extension must not fail the request.

- After the OID_SWITCH_PORT_DELETE request is completed with NDIS_STATUS_SUCCESS, the extension will not receive any packets or OID requests for the deleted port. The extension cannot forward packets to the deleted port. The extension also cannot issue OID requests nor call the *ReferenceSwitchPort* function for the deleted port.

Note Extensible switch extensions must not issue OID set requests of OID_SWITCH_PORT_DELETE.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID set request of OID_SWITCH_PORT_DELETE and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_FEATURE_STATUS_QUERY

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) method request of OID_SWITCH_PORT_FEATURE_STATUS_QUERY to obtain custom status information from an extension about an extensible switch port. This information is known as *feature status* information. The format of this information is defined by the independent software vendor (ISV).

After a successful return from this OID method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS structure that specifies the parameters for the type of feature status information to be returned.
- An NDIS_SWITCH_PORT_FEATURE_STATUS_CUSTOM structure that contains the feature status information for the extensible switch port.

Remarks

For guidelines on how to handle an OID set request of OID_SWITCH_PORT_FEATURE_STATUS_QUERY, see Managing Custom Port Feature Status Information.

Return Status Codes

The extension returns one of the following status codes for the OID method request of OID_SWITCH_PORT_FEATURE_STATUS_QUERY.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the feature status information as well as the NDIS_SWITCH_PORT_FEATURE_STATUS_CUSTOM and NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS structures. The underlying miniport edge of the extensible switch sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS

NDIS_SWITCH_PORT_PROPERTY_TYPE

OID_SWITCH_PORT_PROPERTY_ADD

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_PROPERTY_ADD to notify extensible switch extensions about the addition of a policy property for an extensible switch port.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure that specifies the identification and type of parameters for a port policy.
- A property buffer that contains the parameters for a port policy. The property buffer contains a structure that is based on the **PropertyType** member of the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure. For example, if the **PropertyType** member is set to **NdisSwitchPortPropertyTypeVlan**, the property buffer contains an NDIS_SWITCH_PORT_PROPERTY_VLAN structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PORT_PROPERTY_ADD. All other types of extensions must call NdisFOidRequest to forward the OID request to the next extension in the extensible switch driver stack.

The extension can veto the addition of the port property by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its configured policies on the port, it should veto the addition request.

Note If the extension returns other NDIS_STATUS_*Xxx* error status codes, the creation notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For guidelines on how to handle an OID set request of OID_SWITCH_PORT_PROPERTY_ADD, see Managing Port Policies.

Return Status Codes

If the forwarding extension completes the OID set request of OID_SWITCH_PORT_PROPERTY_ADD, it returns one of the following status codes:

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to process the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure and the data in the structure's property buffer. The extension sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_DATA_NOT_ACCEPTED	The forwarding extension has vetoed the port policy addition notification.
NDIS_STATUS_NOT_SUPPORTED	The forwarding extension does not support the port policy.
NDIS_STATUS_*Xxx*	The OID request failed for other reasons.

If the extension does not complete the OID set request of OID_SWITCH_PORT_PROPERTY_ADD, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code:

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_PROPERTY_DELETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_PROPERTY_DELETE to notify extensible switch extensions about the deletion of a policy property for an extensible switch port.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer that contains an NDIS_SWITCH_PORT_PROPERTY_DELETE_PARAMETERS structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PORT_PROPERTY_DELETE. All other types of extensions must call NdisFOidRequest to forward the OID request to the next extension in the extensible switch driver stack.

For guidelines on how to handle an OID set request of OID_SWITCH_PORT_PROPERTY_DELETE, see Managing Port Policies.

Return Status Codes

If the forwarding extension completes the OID set request of OID_SWITCH_PORT_PROPERTY_DELETE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The forwarding extension does not support the port policy.
NDIS_STATUS_*Xxx*	The OID request failed for other reasons.

If the forwarding extension does not complete the OID set request of OID_SWITCH_PORT_PROPERTY_DELETE, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code.

Status Code	Description

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_PROPERTY_ENUM

Article • 02/18/2023

The Hyper-V extensible switch extension issues an object identifier (OID) method request of OID_SWITCH_PORT_PROPERTY_ENUM to obtain an array. This array contains the provisioned port policies that match the specified criteria. Each element in the array specifies the properties of a policy for a specified extensible switch port.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_PROPERTY_ENUM_PARAMETERS structure that specifies the parameters for the policy enumeration of a specified port.

- An array of NDIS_SWITCH_PORT_PROPERTY_ENUM_INFO structures. Each of these structures contains information about the properties of an extensible switch port policy.

  Note If the **NumProperties** member of the NDIS_SWITCH_PORT_PROPERTY_ENUM_PARAMETERS structure is set to zero, no NDIS_SWITCH_PORT_PROPERTY_ENUM_INFO structures are returned.

Remarks

Before it issues an OID method request of OID_SWITCH_PORT_PROPERTY_ENUM, the extensible switch extension must follow these guidelines:

- The extension can only issue the OID_SWITCH_PORT_PROPERTY_ENUM request after the protocol edge of the extensible switch issues an OID_SWITCH_PORT_CREATE request and before it issues an OID_SWITCH_PORT_TEARDOWN request.

- The extension must call *ReferenceSwitchPort* before it calls **NdisFOidRequest** to issue the OID_SWITCH_PORT_PROPERTY_ENUM request. This ensures that the specified port will not be deleted until after the OID request is completed.

  After the OID request is completed, the extension must call *DereferenceSwitchPort*. The extension must call this function regardless of whether the OID request was completed with NDIS_STATUS_SUCCESS.

The OID_SWITCH_PORT_PROPERTY_ENUM OID must only be issued when the Hyper-V extensible switch has completed activation. Please see Querying the Hyper-V Extensible

Switch Configuration for more details.

Note If the extension receives the OID method request of OID_SWITCH_PORT_PROPERTY_ENUM, it must not complete the OID request. Instead, it must call **NdisFOidRequest** to forward the OID request down the extensible switch driver stack.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_PORT_PROPERTY_ENUM and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_PROPERTY_UPDATE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_PROPERTY_UPDATE to notify extensible switch extensions about the update of a property for an extensible switch port policy.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure that specifies the identification and type of a port property.
- A property buffer that contains the parameters for a port policy. The property buffer contains a structure that is based on the **PropertyType** member of the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure. For example, if the **PropertyType** member is set to **NdisSwitchPortPropertyTypeVlan**, the property buffer contains an NDIS_SWITCH_PORT_PROPERTY_VLAN structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PORT_PROPERTY_UPDATE. All other types of extensions must call NdisFOidRequest to forward the OID request to the next extension in the extensible switch driver stack.

The extension can veto the update of the port property by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its updated policies on the port, it should veto the update request.

Note If the extension returns other NDIS_STATUS_*Xxx* error status codes, the update notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For guidelines on how to handle an OID set request of OID_SWITCH_PORT_PROPERTY_UPDATE, see Managing Port Policies.

Return Status Codes

If the forwarding extension completes the OID set request of OID_SWITCH_PORT_PROPERTY_UPDATE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to process the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS structure and the data in the structure's property buffer. The extension sets the **DATA.SET_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_DATA_NOT_ACCEPTED	The forwarding extension has vetoed the port policy deletion notification.
NDIS_STATUS_NOT_SUPPORTED	The forwarding extension does not support the port policy.
NDIS_STATUS_*Xxx*	The OID request failed for other reasons.

If the extension does not complete the OID set request of OID_SWITCH_PORT_PROPERTY_UPDATE, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_TEARDOWN

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_TEARDOWN to notify underlying extensible switch extensions that an extensible switch port will begin the deletion process. This process is started when the protocol driver issues an OID set request of OID_SWITCH_PORT_DELETE.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PORT_PARAMETERS** structure.

Remarks

The **PortId** member of the **NDIS_SWITCH_PORT_PARAMETERS** structure specifies the extensible switch port for which the connect notification is being made. The extensible switch extension must update any cached information about the port that it obtained in the following ways:

- By issuing OID query requests of OID_SWITCH_PORT_ARRAY. The extension issues this OID on *FilterAttach* only when OID_SWITCH_PARAMETERS returns an **NDIS_SWITCH_PARAMETERS** structure with **IsActive** set to TRUE. If **IsActive** is FALSE, the extension issues the OID when the **NetEventSwitchActivate** **NET_PNP_EVENT** is issued by the extension miniport.

- By inspecting the various OID sets requests of OID_SWITCH_PORT_CREATE and OID_SWITCH_PORT_DELETE.

The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN to notify the extension that a port is in the process of being deleted from the extensible switch. Before this OID request is issued, the protocol edge of the extensible switch had previously issued the following OIDs if the port had an active network adapter connection:

- OID_SWITCH_NIC_DISCONNECT, which notified underlying extensions that the network adapter is no longer connected to the port that is specified in the **NDIS_SWITCH_PORT_PARAMETERS** structure.

- OID_SWITCH_NIC_DELETE, which notified underlying extensions that the network connection between the network adapter and extensible switch port has been deleted.

The protocol edge issues this OID set request after all pending packets for the specified extensible switch port have been canceled or completed.

After the extension completes this OID set request and the reference counter for the extensible switch port is zero, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_DELETE. This OID request deletes the port from the extensible switch.

Note An extension increments the reference counter for an extensible switch port by calling *ReferenceSwitchPort*. An extension decrements the reference counter by calling *DereferenceSwitchPort*.

The extension must follow these guidelines for handling OID set requests of OID_SWITCH_PORT_TEARDOWN:

- The extension must always forward this OID set request to underlying extensions. The extension must not fail the request.

  Note The extension must not modify the **NDIS_SWITCH_PORT_PARAMETERS** structure that is associated with the OID request.

- After the extension forwards this OID request, it cannot forward packets to the deleted port. The extension also cannot issue OID requests nor call the *ReferenceSwitchPort* function for the deleted port.

Note The extension must not issue OID set requests of OID_SWITCH_PORT_TEARDOWN.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID set request of OID_SWITCH_PORT_TEARDOWN and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

Header	Ntddndis.h (include Ndis.h)

OID_SWITCH_PORT_UPDATED

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_UPDATED to notify extensible switch extensions about the update of an extensible switch port. The OID will only be issued for ports that have already been created, and have not yet begun the teardown/delete process. Currently, only the **PortFriendlyName** field is subject to update after creation.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an NDIS_SWITCH_NIC_SAVE_STATE structure.

Remarks

The **PortId** member of the NDIS_SWITCH_PORT_PARAMETERS structure specifies the extensible switch port for which the update notification is being made.

The extension must follow these guidelines for handling OID set requests of OID_SWITCH_PORT_UPDATED:

- The extension must not modify the NDIS_SWITCH_PORT_PARAMETERS structure that is associated with the OID request.

- The extension must always forward this OID set request to underlying extensions. The extension must not fail the request.

Note Extensible switch extensions must not issue OID set requests of OID_SWITCH_PORT_UPDATED.

For more information about the states of extensible switch ports and network adapter connections, see Hyper-V Extensible Switch Port and Network Adapter States.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID set request of OID_SWITCH_PORT_UPDATED and returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SWITCH_PROPERTY_ADD

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PROPERTY_ADD to notify extensible switch extensions about the addition of a switch policy property

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PROPERTY_PARAMETERS structure that specifies the identification and type of an extensible switch policy.

- A property buffer that contains the parameters for an extensible switch policy. The property buffer contains a structure that is based on the **PropertyType** member of the NDIS_SWITCH_PROPERTY_PARAMETERS structure.

  Note Starting with Windows Server 2012, the **PropertyType** member must be set to **NdisSwitchPropertyTypeCustom** and the property buffer must contain an NDIS_SWITCH_PROPERTY_CUSTOM structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PROPERTY_ADD. All other types of extensions must call NdisFOidRequest to forward the OID request to the next extension in the extensible switch driver stack.

The extension can veto the addition of the switch property by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its updated policies on the switch, it should veto the addition request.

Note If the extension returns other NDIS_STATUS_*Xxx* error status codes, the creation notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For guidelines on how to handle an OID set request of OID_SWITCH_PROPERTY_ADD, see Managing Switch Policies.

Return Status Codes

If the forwarding extension completes the OID set request of OID_SWITCH_PROPERTY_ADD, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_DATA_NOT_ACCEPTED	The extension has vetoed the switch policy addition notification.
NDIS_STATUS_FAILURE	The OID request failed for other reasons.

If the extension does not complete the OID set request of OID_SWITCH_PROPERTY_ADD, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

Requirements

OID_SWITCH_PROPERTY_DELETE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PROPERTY_DELETE to notify extensible switch extensions about the deletion of a switch policy property.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer that contains an **NDIS_SWITCH_PROPERTY_DELETE_PARAMETERS** structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PROPERTY_DELETE. All other types of extensions must call **NdisFOidRequest** to forward the OID request to the next extension in the extensible switch driver stack.

For guidelines on how to handle an OID set request of OID_SWITCH_PROPERTY_DELETE, see Managing Switch Policies.

Return Status Codes

If the forwarding extension completes the OID set request of OID_SWITCH_PROPERTY_DELETE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The forwarding extension does not support the switch policy.
NDIS_STATUS_*Xxx*	The OID request failed for other reasons.

If the forwarding extension does not complete the OID set request of OID_SWITCH_PROPERTY_DELETE, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

OID_SWITCH_PROPERTY_ENUM

Article • 02/18/2023

The Hyper-V extensible switch extension issues an object identifier (OID) method request of OID_SWITCH_PROPERTY_ENUM to obtain an array. This array contains the provisioned switch policies that match the specified criteria. Each element in the array specifies the properties of an extensible switch policy.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PROPERTY_ENUM_PARAMETERS structure that specifies the parameters for the extensible switch policy enumeration.

- An array of NDIS_SWITCH_PROPERTY_ENUM_INFO structures. Each of these structures contains information about an extensible switch policy.

  Note If the extension has not been provisioned with instances of the specified extensible switch policy, the extension sets the **NumProperties** member of the NDIS_SWITCH_PROPERTY_ENUM_PARAMETERS structure to zero and no NDIS_SWITCH_PROPERTY_ENUM_INFO structures are returned.

Remarks

The OID_SWITCH_PROPERTY_ENUM OID must only be issued when the Hyper-V extensible switch has completed activation. Please see Querying the Hyper-V Extensible Switch Configuration for more details.

Unlike OID query requests of OID_SWITCH_PORT_PROPERTY_ENUM, the extension does not have to call any *ReferenceSwitchXxx* or *DereferenceSwitchXxx* functions when it issues the OID_SWITCH_PROPERTY_ENUM request down the extensible switch driver stack.

Note If the extension receives the OID method request of OID_SWITCH_PROPERTY_ENUM, it must not complete the OID request. Instead, it must call NdisFOidRequest to forward the OID request down the extensible switch driver stack.

Return Status Codes

The underlying miniport edge of the extensible switch completes the OID query request of OID_SWITCH_PROPERTY_ENUM and returns one of the following status codes.

Status Code	**Description**
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_INVALID_LENGTH	The length of the information buffer is too small to return the NDIS_SWITCH_PROPERTY_ENUM_PARAMETERS structure and its array of NDIS_SWITCH_PROPERTY_ENUM_INFO elements. The underlying miniport edge of the extensible switch sets the **DATA.METHOD_INFORMATION.BytesNeeded** member in the NDIS_OID_REQUEST structure to the minimum buffer size that is required.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Version	Supported in NDIS 6.30 and later.

OID_SWITCH_PROPERTY_UPDATE

Article • 02/18/2023

The protocol edge of the Hyper-V extensible switch issues an object identifier (OID) set request of OID_SWITCH_PROPERTY_UPDATE to notify extensible switch extensions about the update to parameters for an extensible switch policy property.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PROPERTY_PARAMETERS structure that specifies the identification and type of an extensible switch policy.

- A property buffer that contains the parameters for an extensible switch policy. The property buffer contains a structure that is based on the **PropertyType** member of the NDIS_SWITCH_PROPERTY_PARAMETERS structure.

  Note Starting with Windows Server 2012, the **PropertyType** member must be set to **NdisSwitchPropertyTypeCustom** and the property buffer must contain an NDIS_SWITCH_PROPERTY_CUSTOM structure.

Remarks

A forwarding extension can handle the OID set request of OID_SWITCH_PROPERTY_UPDATE. All other types of extensions must call NdisFOidRequest to forward the OID request to the next extension in the extensible switch driver stack.

The extension can veto the update of the switch property by returning NDIS_STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its updated policies on the switch, it should veto the update request.

Note If the extension returns other NDIS_STATUS_*Xxx* error status codes, the creation notification is also vetoed. However, returning status codes for transitory scenarios, such as returning NDIS_STATUS_RESOURCES, could result in a retry of the creation notification.

If the extension does not veto the OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For guidelines on how to handle an OID set request of OID_SWITCH_PROPERTY_UPDATE, see Managing Switch Policies.

Return Status Codes

If the extension completes the OID set request of OID_SWITCH_PROPERTY_UPDATE, it returns one of the following status codes.

Status Code	Description
NDIS_STATUS_DATA_NOT_ACCEPTED	The extension has vetoed the switch policy update notification.
NDIS_STATUS_FAILURE	The OID request failed for other reasons.

If the extension does not complete the OID set request of OID_SWITCH_PROPERTY_UPDATE, the request is completed by the underlying miniport edge of the extensible switch. The miniport edge returns the following status code.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.

OID_TCP_CONNECTION_OFFLOAD_CURRENT_CONFIG

Article • 02/18/2023

As a query request, administrative applications (or possibly overlying drivers) can use the OID_TCP_CONNECTION_OFFLOAD_CURRENT_CONFIG OID to determine the currently-enabled connection offload capabilities of an underlying miniport adapter. A system administrator can use this OID through the Microsoft Windows Management Instrumentation (WMI) interface.

Set requests are not supported.

Remarks

NDIS handles this OID for miniport drivers. Miniport drivers report miniport adapter connection offload settings to NDIS. For information about passing connection offload configuration settings to NDIS from a miniport driver and from NDIS to overlying drivers, see NDIS_TCP_CONNECTION_OFFLOAD.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_TCP_CONNECTION_OFFLOAD structure.

In response to OID_TCP_CONNECTION_OFFLOAD_CURRENT_CONFIG, the **Encapsulation** member of NDIS_TCP_CONNECTION_OFFLOAD defines the current packet encapsulation configuration of the miniport adapter. NDIS provides a bitwise OR of the flags that are provided in the **Encapsulation** member. The other members of NDIS_TCP_CONNECTION_OFFLOAD contain settings for various connection offload services. For more information about encapsulation and other capabilities, see NDIS_TCP_CONNECTION_OFFLOAD and NDIS_OFFLOAD_PARAMETERS.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_CONNECTION_OFFLOAD_HARDWARE_CAPABILITIES

Article • 02/18/2023

As a query request, the OID_TCP_CONNECTION_OFFLOAD_HARDWARE_CAPABILITIES OID reports the current connection offload hardware capabilities of an underlying miniport adapter. User-mode applications (or possibly overlying drivers) can query this OID to determine the connection offload hardware capabilities of an underlying miniport adapter. A system administrator can use this OID through the Microsoft Windows Management Instrumentation (WMI) interface.

Set requests are not supported.

Remarks

NDIS handles this OID for miniport drivers. Miniport drivers report miniport adapter connection offload hardware capabilities to NDIS. For information about passing connection offload hardware capabilities to NDIS from a miniport driver and from NDIS to overlying drivers, see NDIS_TCP_CONNECTION_OFFLOAD.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_TCP_CONNECTION_OFFLOAD structure.

In response to OID_TCP_CONNECTION_OFFLOAD_HARDWARE_CAPABILITIES, the **Encapsulation** member of NDIS_TCP_CONNECTION_OFFLOAD defines the current packet encapsulation hardware capabilities of the miniport adapter. NDIS provides a bitwise OR of the flags that are provided in the **Encapsulation** member. The other members of NDIS_TCP_CONNECTION_OFFLOAD contain settings for various connection offload services. For more information about encapsulation and other capabilities, see NDIS_TCP_CONNECTION_OFFLOAD and NDIS_OFFLOAD_PARAMETERS.

OID_TCP_CONNECTION_OFFLOAD_PARAMETERS

Article • 02/18/2023

As a query request, overlying drivers can use the OID_TCP_CONNECTION_OFFLOAD_PARAMETERS OID to determine the current connection offload settings of an underlying miniport adapter. NDIS handles this OID query for miniport drivers.

As a set request, NDIS and overlying drivers use the OID_TCP_CONNECTION_OFFLOAD_PARAMETERS OID to set the connection offload configuration parameters of an underlying miniport adapter. Miniport drivers that support connection offload must handle this OID set request. Otherwise, the OID_TCP_CONNECTION_OFFLOAD_PARAMETERS OID is optional for miniport drivers.

Remarks

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_TCP_CONNECTION_OFFLOAD_PARAMETERS structure.

> ⓘ Note
>
> Do not confuse OID_TCP_CONNECTION_OFFLOAD_PARAMETERS with the **OID_TCP_OFFLOAD_PARAMETERS** OID that administrative applications use to enable or disable TCP offload features.

NDIS_OID_REQUEST
OID_TCP_OFFLOAD_PARAMETERS

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_OFFLOAD_CURRENT_CONFIG

Article • 02/18/2023

As a query request, administrative applications (or possibly overlying drivers) use the OID_TCP_OFFLOAD_CURRENT_CONFIG OID to determine the current task offload configuration settings of an underlying miniport adapter. A system administrator can use this OID through the Microsoft Windows Management Instrumentation (WMI) interface.

Set requests are not supported.

Remarks

NDIS handles this OID for miniport drivers. Miniport drivers report miniport adapter offload capabilities to NDIS. For information about passing task offload configuration settings to NDIS from a miniport driver and from NDIS to overlying drivers, see NDIS_OFFLOAD.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_OFFLOAD structure. The **NDIS_OFFLOAD** structure includes the following miniport adapter capabilities:

- The header information, which includes the task offload version.
- The checksum offload information, in an NDIS_TCP_IP_CHECKSUM_OFFLOAD structure.
- The large send offload version 1 (LSOV1) information, in an NDIS_TCP_LARGE_SEND_OFFLOAD_V1 structure.
- The Internet protocol security (IPsec) information, in an NDIS_IPSEC_OFFLOAD_V1 structure.
- The large send offload version 2 (LSOV2) information, in an NDIS_TCP_LARGE_SEND_OFFLOAD_V2 structure.

In response to OID_TCP_OFFLOAD_CURRENT_CONFIG, the **Encapsulation** members of the structures in the preceding list define the packet encapsulation capabilities of the miniport adapter. NDIS provides a bitwise OR of the flags that are provided in the **Encapsulation** members of these structures. The other structure members contain settings for various offload services. For more information about encapsulation and other capabilities, see NDIS_TCP_IP_CHECKSUM_OFFLOAD, NDIS_TCP_LARGE_SEND_OFFLOAD_V1, NDIS_IPSEC_OFFLOAD_V1, and NDIS_TCP_LARGE_SEND_OFFLOAD_V2.

Miniport adapters must support Ethernet encapsulation for all of the types of task offload that they support. The other types of encapsulation are optional.

Miniport drivers should automatically enable all of the task offload capabilities during initialization.

OID_TCP_OFFLOAD_HARDWARE_CAPABILITIES

Article • 02/18/2023

As a query request, the OID_TCP_OFFLOAD_HARDWARE_CAPABILITIES OID reports the task offload hardware capabilities of a miniport adapter's hardware. User-mode applications (or possibly overlying drivers) can query this OID to determine the task offload hardware capabilities of an underlying miniport adapter. A system administrator can use this OID through the Windows Management Instrumentation (WMI) interface.

Set requests are not supported.

Remarks

NDIS handles this OID for miniport drivers. Miniport drivers report miniport adapter hardware capabilities to NDIS. For information about reporting task offload hardware capabilites to NDIS from a miniport driver and from NDIS to overlying drivers, see NDIS_OFFLOAD.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_OFFLOAD structure. NDIS returns NDIS_STATUS_BUFFER_TOO_SHORT if the buffer is not big enough.

After determining the miniport adapter's hardware capabilities, the overlying applications or drivers can use the OID_TCP_OFFLOAD_PARAMETERS OID to enable capabilities that are currently reported as not enabled by the OID_TCP_OFFLOAD_CURRENT_CONFIG OID.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_OFFLOAD_PARAMETERS

Article • 02/18/2023

Query requests are not supported.

As a set request, the OID_TCP_OFFLOAD_PARAMETERS OID sets the current TCP offload configuration of a miniport adapter. Protocol drivers or user-mode applications can set this OID to change the current TCP offload configuration. A system administrator can use this OID through the Microsoft Windows Management Instrumentation (WMI) interface.

Remarks

OID_TCP_OFFLOAD_PARAMETERS is required for miniport drivers that support TCP offloads and optional for other miniport drivers. If a miniport driver does not support this OID, the driver should return NDIS_STATUS_NOT_SUPPORTED.

The **InformationBuffer** member of the NDIS_OID_REQUEST structure contains an NDIS_OFFLOAD_PARAMETERS structure. If the contents of **InformationBuffer** are invalid, the miniport driver should return NDIS_STATUS_INVALID_DATA in response to this OID.

While NDIS processes this OID and before it passes the OID to the miniport driver, NDIS updates the miniport adapter's offload standardized keywords with the new settings.

Miniport drivers must use the contents of the NDIS_OFFLOAD_PARAMETERS structure to update the currently reported TCP offload capabilities. After the update, the miniport driver must report the current task offload capabilities with the NDIS_STATUS_TASK_OFFLOAD_CURRENT_CONFIG status indication. This status indication ensures that all of the overlying protocol drivers are updated with the new capabilities information.

This OID is a more comprehensive OID that instructs miniport drivers to turn certain offloads on or off. Most TCP/IP task offloads can be configured and activated with this OID. For some offloads, such as Rx Checksum or Rx IPSec, this OID serves as a configuration change and doesn't mean the offload will be operational immediately. To activate those offloads, the miniport driver must wait until it receives an OID_OFFLOAD_ENCAPSULATION Set request.

Before setting OID_TCP_OFFLOAD_PARAMETERS, the overlying applications or drivers can use the OID_TCP_OFFLOAD_HARDWARE_CAPABILITIES OID to determine what capabilities a miniport adapter's hardware can support. Use

OID_TCP_OFFLOAD_PARAMETERS to enable capabilities that are reported as not enabled by the OID_TCP_OFFLOAD_CURRENT_CONFIG OID.

OID_TCP_RSC_STATISTICS

Article • 02/18/2023

As a query, NDIS and overlying drivers or user-mode applications use the OID_TCP_RSC_STATISTICS OID to get the receive-segment coalescing (RSC) statistics of a miniport adapter.

NDIS 6.30 and later miniport drivers that provide RSC services must support this OID. Otherwise, this OID is optional.

Remarks

The **InformationBuffer** member of NDIS_OID_REQUEST structure contains an NDIS_RSC_STATISTICS_INFO structure.

The miniport driver must maintain the statistics in the members of the NDIS_RSC_STATISTICS_INFO structure as follows:

- The driver must increment the coalesced packet count in the **CoalescedPkts** member by one every time a packet is added to a single coalesced unit (SCU).
- The driver must increment the coalesced octet count in the **CoalescedOctets** member by the size of the TCP payload of the packet every time a packet is added to a SCU.
- The driver must increment the coalesced events count **CoalesceEvents** member by one every time a SCU is finalized. All such SCUs should have a non-zero **CoalescedSegCount** value.
- The driver must increment the abort count in the **Aborts** member by one every time it encounters an exception other than the IP datagram length being exceeded. This count should include the cases where a packet is not coalesced because of hardware resources.

Requirements

Version	Supported for NDIS 6.30 and later drivers in Windows 8.
Header	Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_ADD_SA

Article • 02/18/2023

The OID_TCP_TASK_IPSEC_ADD_SA OID is set by the transport protocol to request that a miniport driver add one or more security associations (SAs) to a NIC.

The information for each SA is formatted as an OFFLOAD_IPSEC_ADD_SA structure.

The first seven members of the OFFLOAD_IPSEC_ADD_SA structure (**SrcAddr**, **SrcMask**, **DestAddr**, **DestMask**, **Protocol**, **SrcPort**, and **DestPort**) constitute a filter that specifies the source and destination, as well as the IP protocols, to which the SAs apply. This filter pertains to a transport-mode connection--that is, an end-to-end connection between two hosts. If the specified connection is made through a tunnel, the source and destination addresses of the tunnel are specified by **SrcTunnelAddr** and **DestTunnelAddr**, respectively.

If a filter parameter is set to zero, that parameter is not used to filter packets for the specified SAs. For example, if **SrcAddr** is set to zero, the specified SAs can apply to a packet that contains any source address. To take this to the extreme, if all the filter parameters are set to zero, the specified SAs apply to any source host sending any type of packet to any destination host.

The TCP/IP transport can specify an IP protocol in the **Protocol** member to indicate that the specified SAs apply only to packets of the specified protocol type. If **Protocol** is set to zero, the specified SAs apply to all packets sent from the specified source to the specified destination.

OFFLOAD_SECURITY_ASSOCIATION structure

An OFFLOAD_SECURITY_ASSOCIATION structure specifies a single security association (SA). The OFFLOAD_SECURITY_ASSOCIATION structure is an element in the **SecAssoc** variable-length array. **SecAssoc** contains one or two OFFLOAD_SECURITY_ASSOCIATION structures.

An SA specified for use in processing authentication headers (AH) will have an operation type of **AUTHENTICATE** and will have an **IntegrityAlgo** (integrity algorithm). The SA will not have an a **ConfAlgo** (confidentiality algorithm). In this case, **ConfAlgo** will contain zeros.

An SA specified for use in processing encapsulating security payloads (ESPs) will have an operation type of **ENCRYPT** and may have an **IntegrityAlgo** (integrity algorithm) and/or a **ConfAlgo** (confidentiality algorithm).

OFFLOAD_ALGO_INFO structure

The OFFLOAD_ALGO_INFO structure, which is a member of an OFFLOAD_SECURITY_ASSOCIATION structure, specifies an algorithm used for a security association (SA).

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_ADD_UDPESP_SA

Article • 02/18/2023

A transport protocol sets OID_TCP_TASK_IPSEC_ADD_UDPESP_SA to request a miniport driver to add one or more security associations (SAs) for UDP-encapsulated ESP packets to a NIC.

The information for each SA is formatted as an OFFLOAD_IPSEC_ADD_UDPESP_SA structure. Note that this structure is almost identical to the OFFLOAD_IPSEC_ADD_SA structure used in the OID_TCP_TASK_IPSEC_ADD_SA request. The only difference is that the OFFLOAD_IPSEC_ADD_UDPESP_SA structure contains the **EncapTypeEntry** and the **EncapTypeEntryOffldHandle** members.

The first seven members of the OFFLOAD_IPSEC_ADD_UDPESP_SA structure (**SrcAddr**, **SrcMask**, **DestAddr**, **DestMask**, **Protocol**, **SrcPort**, and **DestPort**) constitute a filter that specifies the source and destination, as well as the IP protocols, to which the SAs apply. This filter pertains to a transport-mode connection--that is, an end-to-end connection between two hosts. If the specified connection is made through a tunnel, the source and destination addresses of the tunnel are specified by **SrcTunnelAddr** and **DestTunnelAddr**, respectively.

If a filter parameter is set to zero, that parameter is not used to filter packets for the specified SAs. For example, if **SrcAddr** is set to zero, the specified SAs can apply to a packet that contains any source address. To take this to the extreme, if all the filter parameters are set to zero, the specified SAs apply to any source host sending any type of packet to any destination host.

The TCP/IP transport can specify an IP protocol in the **Protocol** member to indicate that the specified SAs apply only to packets of the specified protocol type. If **Protocol** is set to zero, the specified SAs apply to all packets sent from the specified source to the specified destination.

OFFLOAD_SECURITY_ASSOCIATION structure

An OFFLOAD_SECURITY_ASSOCIATION structure specifies a single security association (SA). The OFFLOAD_SECURITY_ASSOCIATION structure is an element in the **SecAssoc** variable-length array. **SecAssoc** contains one or two OFFLOAD_SECURITY_ASSOCIATION structures.

An SA specified for use in processing authentication headers (AH) will have an operation type of **AUTHENTICATE** and will have an **IntegrityAlgo** (integrity algorithm). The SA will not have an a **ConfAlgo** (confidentiality algorithm). In this case, **ConfAlgo** will contain zeros.

An SA specified for use in processing encapsulating security payloads (ESPs) will have an operation type of **ENCRYPT** and may have an **IntegrityAlgo** (integrity algorithm) and/or a **ConfAlgo** (confidentiality algorithm).

OFFLOAD_ALGO_INFO structure

The OFFLOAD_ALGO_INFO structure, which is a member of an OFFLOAD_SECURITY_ASSOCIATION structure, specifies an algorithm used for a security association (SA).

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_DELETE_SA

Article • 02/18/2023

The OID_TCP_TASK_IPSEC_DELETE_SA OID is set by a transport protocol to request that a miniport driver delete a security association (SA) from a NIC. The SA information is formatted as an OFFLOAD_IPSEC_DELETE_SA structure.

On receiving this request, the miniport driver should delete the specified SA from the NIC and free any system resources allocated for the SA.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_DELETE_UDPESP_SA

Article • 02/18/2023

A transport protocol sets OID_TCP_TASK_IPSEC_DELETE_UDPESP_SA to request that a miniport driver delete a UDP-ESP security association (SA) and, possibly, a parser entry from a NIC parser entry list. The SA and parser entry information is formatted as an OFFLOAD_IPSEC_DELETE_UDPESP_SA structure.

If the **EncapTypeEntryOffldHandle** is **NULL**, the miniport should delete the specified SA from the NIC and free any system resources allocated for the SA. If the **EncapTypeEntryOffldHandle** is non-**NULL**, the miniport should also delete the specified parser entry from the NIC's parser entry list.

Note that a transport protocol could request a miniport to delete an SA and/or parser entry before the miniport has completed adding that SA and/or parser entry. The miniport must therefore serialize the deletion operation with the addition operation.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA

Article • 02/18/2023

[The IPsec Task Offload feature is deprecated and should not be used.]

As a set, the TCP/IP transport uses the OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA OID to request that a miniport driver add the specified security associations (SAs) to a NIC.

Note NDIS supports this OID with the direct OID request interface. For more information about the direct OID request interface, see NDIS 6.1 Direct OID Request Interface.

Note This OID is supported in NDIS 6.1 and 6.20. For NDIS 6.30 and later drivers see OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX.

Remarks

All NDIS 6.1 and 6.20 miniport drivers that support IPsec offload version 2 (IPsecOV2) must support this OID.

After TCP/IP transport determines that a NIC can perform IPsecOV2 operations, the TCP/IP transport requests the miniport driver to add SAs. The transport cannot offload IPsecOV2 operations to the NIC before the transport adds an SA.

The miniport driver receives an **IPSEC_OFFLOAD_V2_ADD_SA** structure that contains a pointer to the next IPSEC_OFFLOAD_V2_ADD_SA structure in a linked list. The miniport driver configures the NIC for IPsecOV2 processing on the SAs. With a successful set to OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA, the miniport driver supplies the handles that identify the offloaded SAs in the **OffloadHandle** member of IPSEC_OFFLOAD_V2_ADD_SA. (For example, the transport uses the handle in the send path to indicate which offloaded SA to use). If any of the SAs in the linked list were offloaded, the set request is successful.

The miniport driver can return a failure status for the OID request, for example, when the NIC runs out of capacity to offload more SAs. Also, the miniport driver might return a failure status because it needs to avoid a race condition. In this case, the NIC configuration changes and excludes a particular algorithm.

If the request fails, none of the SAs in the linked list were offloaded. If failure occurs for a particular SA in the linked list, the miniport driver should set the **OffloadHandle** member in the corresponding IPSEC_OFFLOAD_V2_ADD_SA structure to **NULL**.

The miniport driver reports the maximum number of SAs that a NIC can support in the **SaOffloadCapacity** member of the **NDIS_IPSEC_OFFLOAD_V2** structure during initialization. If necessary, the TCP/IP transport can set the OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA OID to request that the miniport driver delete an SA from the NIC.

Requirements

Version	Supported in NDIS 6.1 and 6.20. For NDIS 6.30 and later, use OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX.
Header	Ntddndis.h (include Ndis.h)

See also

IPSEC_OFFLOAD_V2_ADD_SA

NDIS_IPSEC_OFFLOAD_V2

OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX

OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA

OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX

Article • 02/18/2023

[The IPsec Task Offload feature is deprecated and should not be used.]

As a set, the TCP/IP transport uses the OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX OID to request that a miniport driver add the specified security associations (SAs) to a NIC.

Note NDIS supports this OID with the direct OID request interface. For more information about the direct OID request interface, see NDIS 6.1 Direct OID Request Interface.

Remarks

All NDIS 6.30 miniport drivers that support IPsec offload version 2 (IPsecOV2) must support this OID.

After TCP/IP transport determines that a NIC can perform IPsecOV2 operations, the TCP/IP transport requests the miniport driver to add SAs. The transport cannot offload IPsecOV2 operations to the NIC before the transport adds an SA.

The miniport driver configures the NIC for IPsecOV2 processing on the SAs. With a successful set to OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX, the miniport driver supplies the handle that identifies the offloaded SA in the **OffloadHandle** member of the **IPSEC_OFFLOAD_V2_ADD_SA_EX** structure. (For example, the transport uses the handle in the send path to indicate which offloaded SA to use). If an SA was offloaded, the set request is successful.

The miniport driver can return a failure status for the OID request, for example, when the NIC runs out of capacity to offload more SAs. Also, the miniport driver might return a failure status because it needs to avoid a race condition. In this case, the NIC configuration changes and excludes a particular algorithm.

If the request fails, SAs were not offloaded. If failure occurs for an SA, the miniport driver should set the **OffloadHandle** member in the corresponding IPSEC_OFFLOAD_V2_ADD_SA_EX structure to **NULL**.

The miniport driver reports the maximum number of SAs that a NIC can support in the **SaOffloadCapacity** member of the **NDIS_IPSEC_OFFLOAD_V2** structure during initialization. If necessary, the TCP/IP transport can set the OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA OID to request that the miniport driver delete an SA from the NIC.

This OID is essentially identical to the previous version, OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA. The only difference is the updated **IPSEC_OFFLOAD_V2_ADD_SA_EX** structure.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ntddndis.h (include Ndis.h)

See also

IPSEC_OFFLOAD_V2_ADD_SA_EX

NDIS_IPSEC_OFFLOAD_V2

OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA

OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA

OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA

Article • 02/18/2023

[The IPsec Task Offload feature is deprecated and should not be used.]

As a set, the TCP/IP transport uses the OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA OID to request that a miniport driver delete the specified security associations (SAs) from a NIC.

Note NDIS supports this OID with the direct OID request interface. For more information about the direct OID request interface, see NDIS 6.1 Direct OID Request Interface.

Remarks

All NDIS 6.1 miniport drivers that support IPsec offload version 2 (IPsecOV2) must support this OID.

When a miniport driver receives this request, the driver should delete the specified SAs from the NIC and free any system resources that were allocated for the SAs.

The miniport driver receives an **IPSEC_OFFLOAD_V2_DELETE_SA** structure that contains a handle to an SA bundle and a pointer to the next **IPSEC_OFFLOAD_V2_DELETE_SA** structure in a linked list.

The miniport driver can set **SaDeleteReq** in the **NDIS_IPSEC_OFFLOAD_V2_NET_BUFFER_LIST_INFO** structure for a receive **NET_BUFFER_LIST** structure. The TCP/IP transport subsequently issues OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA once to delete the inbound SA that the packet was received over and once again to delete the outbound SA that corresponds to the deleted inbound SA. The NIC must not remove either of these SAs before receiving the corresponding OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA request.

Return status codes

The miniport driver's *MiniportOidRequest* function returns one of the following values for this request:

Term	Description

Term	Description
NDIS_STATUS_SUCCESS	The miniport driver completed the request successfully.
NDIS_STATUS_PENDING	The miniport driver will complete the request asynchronously. After the miniport driver has completed all processing, it must succeed the request by calling the NdisMOidRequestComplete function, passing **NDIS_STATUS_SUCCESS** for the *Status* parameter.
NDIS_STATUS_NOT_ACCEPTED	The miniport driver is resetting.
NDIS_STATUS_REQUEST_ABORTED	The miniport driver stopped processing the request. For example, NDIS called the *MiniportResetEx* function.

Requirements

Version	Supported in NDIS 6.1 and later.
Header	Ntddndis.h (include Ndis.h)

OID_TCP_TASK_IPSEC_OFFLOAD_V2_UPDATE_SA

Article • 02/18/2023

[The IPsec Task Offload feature is deprecated and should not be used.]

As a set, the TCP/IP transport uses the OID_TCP_TASK_IPSEC_OFFLOAD_V2_UPDATE_SA OID to request that a miniport driver update the specified security associations (SAs) on a NIC.

Note NDIS supports this OID with the direct OID request interface. For more information about the direct OID request interface, see NDIS 6.1 Direct OID Request Interface.

Remarks

All NDIS 6.1 miniport drivers that support IPsec offload version 2 (IPsecOV2) must support this OID.

When a miniport driver receives this request, the driver should update the specified SAs on the NIC. The miniport driver can fail this request if the SA is not found or the ESN is not supported. In this case, the returned status should be NDIS_STATUS_INVALID_PARAMETER.

The miniport driver receives an **IPSEC_OFFLOAD_V2_UPDATE_SA** structure that contains information about the update and a pointer to the next IPSEC_OFFLOAD_V2_UPDATE_SA structure in a linked list.

Requirements

Version	Supported in NDIS 6.1 and later.
Header	Ntddndis.h (include Ndis.h)

See also

IPSEC_OFFLOAD_V2_UPDATE_SA

OID_TCP_TASK_OFFLOAD

Article • 02/18/2023

The host stack queries the OID_TCP_TASK_OFFLOAD OID to obtain the TCP offload capabilities of a miniport driver's NIC or of an offload target. After determining the offload capabilities that a NIC or an offload target supports, the host stack sets this OID to enable one or more of the reported capabilities. The host stack can also disable all of a NIC's or an offload target's TCP offload capabilities by setting OID_TCP_TASK_OFFLOAD. Only one protocol at a time can enable the TCP offload capabilities of a particular NIC.

Querying offload capabilities

When the host stack queries OID_TCP_TASK_OFFLOAD, it supplies in the *InformationBuffer* an NDIS_TASK_OFFLOAD_HEADER structure. This structure specifies the following:

- The offload version supported by the host stack.
- The encapsulation format for send and receive packets processed by the host stack.
- The size of the encapsulation header in such packets.

With this information, a miniport driver or its NIC can locate the beginning of the first IP header in a transmit packet, which is a prerequisite for performing an offload task. An offload target needs to know the encapsulation format to process receive packets. In response to a query of OID_TCP_TASK_OFFLOAD, a miniport driver or offload target returns, in the *InformationBuffer*, the NDIS_TASK_OFFLOAD_HEADER structure followed immediately by one or more NDIS_TASK_OFFLOAD structures. Each NDIS_TASK_OFFLOAD structure describes an offload capability supported by the miniport driver's NIC or by the offload target. If the miniport driver's NIC or the offload target supports multiple versions of a particular offload capability, it should return one NDIS_TASK_OFFLOAD structure for each version.

Each NDIS_TASK_OFFLOAD structure has a **Task** member that specifies the particular offload capability to which the structure applies. Each NDIS_TASK_OFFLOAD structure also has a **TaskBuffer** that contains information pertinent to the specified offload capability. The information in the **TaskBuffer** is formatted as one of the following structures:

- NDIS_TASK_TCP_IP_CHECKSUM
  Specifies checksum offload capabilities.

- NDIS_TASK_IPSEC
  Specifies Internet Protocol security (IPsec) offload capabilities.
- NDIS_TASK_TCP_LARGE_SEND
  Specifies large TCP packet segmentation capabilities.
- NDIS_TASK_TCP_CONNECTION_OFFLOAD
  Specifies TCP chimney offload capabilities. For more information on NDIS_TASK_TCP_CONNECTION_OFFLOAD, see TCP Chimney Offload.

> ⓘ Note
>
> If an intermediate driver modifies the contents of packets that it forwards to an underlying miniport driver such that TCP offload functions cannot be performed on the packets, the intermediate driver should respond to OID_TCP_TASK_OFFLOAD queries with a status of NDIS_STATUS_NOT_SUPPORTED instead of passing the OID request to the underlying miniport driver or offload target.

Enabling offload capabilities

After querying a NIC's or an offload target's offload capabilities, the host stack enables one or more of these capabilities by setting OID_TCP_TASK_OFFLOAD. When setting OID_TCP_TASK_OFFLOAD, the host stack supplies, in the *InformationBuffer*, an NDIS_TASK_OFFLOAD_HEADER structure followed immediately by an NDIS_TASK_OFFLOAD structure for each offload capability that the host stack is enabling.

The **Task** in each NDIS_TASK_OFFLOAD structure indicates the offload capability that the host stack is enabling. The host stack also enables specific aspects of a particular offload capability by setting members of the structure in the **TaskBuffer** of each NDIS_TASK_OFFLOAD structure.

Changing offload capabilities

To change the offload capabilities that are enabled for a NIC or an offload target, the host stack sets OID_TCP_TASK_OFFLOAD. The miniport driver or offload target must enable only those offload capabilities specified by the most recent set of OID_TCP_TASK_OFFLOAD. The miniport driver or offload target must disable all other offload capabilities. Note that before disabling a specific TCP chimney offload capability, the host stack terminates the offload of any offloaded TCP connections that use that capability.

An offload target can use pause or resume offload indications to change its reported TCP offload capabilities:

- An offload target makes a pause indication by calling the NdisMIndicateStatusEx function with the NDIS_STATUS_INDICATION->**StatusCode** member set to NDIS_STATUS_OFFLOAD_PAUSE.
- An offload target makes a resume indication by calling the **NdisMIndicateStatusEx** function with the NDIS_STATUS_INDICATION->**StatusCode** member set to NDIS_STATUS_OFFLOAD_RESUME.

After an offload target requests the host stack to resume offloading state objects, the host stack queries OID_TCP_TASK_OFFLOAD again to obtain the offload target's TCP offload revised capabilities. For more information, see NDIS_STATUS_OFFLOAD_RESUME.

Disabling offload capabilities

To disable all offload capabilities supported by a NIC or an offload target, the host stack sets OID_TCP_TASK_OFFLOAD. In the *InformationBuffer*, the host stack supplies an NDIS_TASK_OFFLOAD_HEADER structure with the **OffsetFirstTask** member of this structure set to zero.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP4_OFFLOAD_STATS

Article • 02/18/2023

The host stack queries the OID_TCP4_OFFLOAD_STATS OID to obtain statistics on TCP segments that an offload target has processed on offloaded TCP connections that convey IPv4 datagrams. The host stack sets this OID to cause an offload target to reset the counters for such statistics to zero.

In response to a query of OID_TCP4_OFFLOAD_STATS, an offload target supplies a filled-in TCP_OFFLOAD_STATS structure.

In response to a set of OID_TCP4_OFFLOAD_STATS, an offload target should reset to zero all of its TCP statistics counters for offloaded TCP connections that convey IPv4 datagrams.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TCP6_OFFLOAD_STATS

Article • 02/18/2023

The host stack queries the OID_TCP6_OFFLOAD_STATS OID to obtain statistics on TCP segments that an offload target has processed on offloaded TCP connections that convey IPv6 datagrams. The host stack sets this OID to cause an offload target to reset the counters for such statistics to zero.

In response to a query of OID_TCP6_OFFLOAD_STATS, an offload target supplies a filled-in TCP_OFFLOAD_STATS structure.

In response to a set of OID_TCP6_OFFLOAD_STATS, an offload target should reset to zero all of its TCP statistics counters for offloaded TCP connections that convey IPv6 datagrams.

Requirements

Version: Windows Vista and later **Header**: Ntddndis.h (include Ndis.h)

OID_TIMESTAMP_CAPABILITY

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_TIMESTAMP_CAPABILITY to obtain the hardware timestamping capabilities of the NIC and software timestamping capabilities of the miniport driver.

The **RequestType** member of the **NDIS_OID_REQUEST** structure will be **NdisRequestQueryInformation**.

NDIS handles this OID for the miniport driver based on the information the miniport driver provided in the **NDIS_STATUS_TIMESTAMP_CAPABILITY** status indication.

Requirements

Requirement	**Value**
Minimum supported client	Windows 11
Minimum supported server	Windows Server 2022
NDIS Version	NDIS 6.82 and later
Header	Ntddndis.h (include Ndis.h)

OID_TIMESTAMP_GET_CROSSTIMESTAMP

NDIS_OID_REQUEST

OID_TIMESTAMP_GET_CROSSTIMESTAMP

Article • 02/18/2023

An overlying driver issues an object identifier (OID) query request of OID_TIMESTAMP_GET_CROSSTIMESTAMP to obtain a cross timestamp from the NIC hardware. A cross timestamp is the set of a NIC hardware timestamp and system timestamp(s) obtained very close to each other. Precision Time Protocol (PTP) version 2 applications use the information provided in this OID to establish a relation between the NIC's hardware clock and a system clock.

The miniport driver must support this OID if it sets the **CrossTimestamp** field to **TRUE** in the NDIS_TIMESTAMP_CAPABILITIES structure as part of the current configuration. For more details on reporting the current configuration, see the NDIS_STATUS_TIMESTAMP_CURRENT_CONFIG status indication. If the cross timestamping ability is disabled, then the OID should be completed with an appropriate error code (for example, NDIS_STATUS_NOT_SUPPORTED).

The **RequestType** member of the NDIS_OID_REQUEST structure will be **NdisRequestQueryInformation**.

When a miniport driver receives the OID request of OID_TIMESTAMP_GET_CROSSTIMESTAMP, the driver completes the OID by filling the **InformationBuffer** in the **QUERY_INFORMATION** with an NDIS_HARDWARE_CROSSTIMESTAMP structure. The **Type** field in the **Header** field of the **NDIS_HARDWARE_CROSSTIMESTAMP** structure should be set to **NDIS_OBJECT_TYPE_DEFAULT** and the **Revision** field to **NDIS_HARDWARE_CROSSTIMESTAMP_REVISION_1**. The driver should fill the **SystemTimestamp1**, **HardwareClockTimestamp** and **SystemTimestamp2** fields with following timestamps taken as close to each other as possible and in the following order:

1. **SystemTimestamp1**: Performance counter value (QPC) obtained by calling KeQueryPerformanceCounter.

2. **HardwareClockTimestamp**: The NIC hardware clock's current value. This should be the raw hardware clock value of the NIC.

3. **SystemTimestamp2**: Another performance counter value (QPC) obtained by calling **KeQueryPerformanceCounter**.

Here's an example of how a miniport driver handles OID_TIMESTAMP_GET_CROSSTIMESTAMP:

C++

```
{
. . .
    NDIS_HARDWARE_CROSSTIMESTAMP crossTimestamp;
    LARGE_INTEGER timeStamp;

    RtlZeroMemory(&crossTimestamp, sizeof(crossTimestamp));

    timeStamp = KeQueryPerformanceCounter(NULL);
    crossTimestamp.SystemTimestamp1 = timeStamp.QuadPart;
    crossTimestamp.HardwareClockTimestamp =
FunctionToRetrieveHardwareTimestampFromNetworkCard();
    timeStamp = KeQueryPerformanceCounter(NULL);
    crossTimestamp.SystemTimestamp2 = timeStamp.QuadPart;
    crossTimestamp.Header.Type = NDIS_OBJECT_TYPE_DEFAULT;
    crossTimestamp.Header.Size =
NDIS_SIZEOF_HARDWARE_CROSSTIMESTAMP_REVISION_1;
    crossTimestamp.Header.Revision =
NDIS_HARDWARE_CROSSTIMESTAMP_REVISION_1;

// Complete the OID by filling the query information buffer with the
crossTimestamp
}
```

The **Flags** field in the **NDIS_HARDWARE_CROSSTIMESTAMP** structure is reserved for future use. The miniport driver must not change its value.

The miniport driver and hardware are free to optimize the collection of these timestamps depending on any advanced hardware capabilities. However, the **SystemTimestamp1** and **SystemTimestamp2** values returned on OID completion must accurately correspond to the performance counter (QPC) value at the time of capture. The **HardwareClockTimestamp** must correspond to the NIC's hardware clock value at the point of capture. If a particular implementation can more accurately determine two timestamps rather than three (for example, one system timestamp and the corresponding NIC hardware clock timestamp), then it should set the **SystemTimestamp2** field to the same value as **SystemTimestamp1**.

The miniport driver should not set the **SystemTimestamp1**, **HardwareClockTimestamp**, or **SystemTimestamp2** values to **zero**.

Return Status Codes

The miniport driver returns one of the following status codes for the OID query request of OID_TIMESTAMP_GET_CROSSTIMESTAMP.

Status Code	Description
NDIS_STATUS_SUCCESS	The OID request completed successfully.
NDIS_STATUS_NOT_SUPPORTED	The miniport driver either does not support cross timestamping or the cross timestamping ability is disabled.
NDIS_STATUS_FAILURE	The request failed for other reasons.

Requirements

Requirement	Value
Minimum supported client	Windows 11
Minimum supported server	Windows Server 2022
NDIS Version	NDIS 6.82 and later

OID_WAN_CO_GET_COMP_INFO

Article • 02/18/2023

The OID_WAN_CO_GET_COMP_INFO OID requests the miniport driver to return information about the capabilities of the NIC or of its driver, in particular whether either supports compression. If so, the values returned are used to negotiate compression with the Point-to-Point Protocol (PPP) Compression Control Protocol. The protocol subsequently negotiates a PPP compression scheme with an OID_WAN_CO_SET_COMP_INFO request. This compression information is specific to a virtual connection (VC).

Compression information is returned in an NDIS_WAN_CO_GET_COMP_INFO structure, defined as follows:

ManagedCPlusPlus

```
    typedef struct _NDIS_WAN_CO_GET_COMP_INFO {
         OUT NDIS_WAN_COMPRESS_INFO SendCapabilities;
         OUT NDIS_WAN_COMPRESS_INFO RecvCapabilities;
    } NDIS_WAN_CO_GET_COMP_INFO,   *PNDIS_WAN_CO_GET_COMP_INFO;
```

The members of this structure contain the following information:

SendCapabilities
Specifies a structure containing information about compression capabilities for sending data.

RecvCapabilities
Specifies a structure containing information about compression capabilities for receiving data.

Remarks

For specifics of the NDIS_WAN_COMPRESS_INFO structure, see OID_WAN_GET_COMP_INFO.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.

Header	Ntddndis.h (include Ndis.h)

OID_WAN_GET_COMP_INFO

OID_WAN_CO_SET_COMP_INFO

OID_WAN_CO_GET_INFO

Article • 02/18/2023

The OID_WAN_CO_GET_INFO OID requests the miniport driver to return information that applies to all virtual connections (VCs) on its NIC. This information is returned in an NDIS_WAN_CO_INFO structure, defined as follows.

ManagedCPlusPlus

```
    typedef struct _NDIS_WAN_CO_INFO {
         OUT ULONG MaxFrameSize;
         OUT ULONG MaxSendWindow;
         OUT ULONG FramingBits;
         OUT ULONG DesiredACCM;
    } NDIS_WAN_CO_INFO, *PNDIS_WAN_CO_INFO;
```

The members of this structure contain the following information:

MaxFrameSize
Specifies the maximum frame size for any net packet that the miniport driver can send and receive. This value should exclude the miniport driver's own framing overhead and/or the PPP HDLC overhead. Typically this value is around 1500.

However, all CoNDIS WAN miniport drivers should use an internal **MaxFrameSize** that is 32 bytes larger than the value they return for this OID. For example, a CoNDIS WAN miniport driver that returns 1500 for this OID should internally accept and send up to 1532. Such a miniport driver can readily support future bridging and additional protocols.

MaxSendWindow
Specifies the maximum number of outstanding packets that the CoNDIS WAN miniport driver can handle on a VC. This member must be set to at least one.

The NDISWAN driver uses the value of this member as a limit on how many packets it submits in send requests to the miniport driver's *MiniportCoSendPackets* function before NDISWAN holds send packets. These packets are queued until the miniport driver completes an outstanding send. A miniport driver can adjust this value dynamically and on a per-VC basis using the **SendWindow** member in the WAN_CO_LINKPARAMS structure that the miniport driver passes to NdisMCoIndicateStatus. NDISWAN uses the current **SendWindow** value as its limit on outstanding sends. If the miniport driver sets **SendWindow** to zero, NDISWAN must stop sending packets for the particular VC. That is, the miniport driver specifies that the send window is shut down, which, in effect, specifies that it cannot accept any packets from NDISWAN.

Because a CoNDIS WAN miniport driver must queue packets internally, the value of **MaxSendWindow** is theoretically **max**(ULONG). However, this driver-determined value should reflect the link speed or hardware capabilities of the NIC. For example, if a miniport driver's NIC always has room for at least four packets, the miniport driver sets **MaxSendWindow** to four so that any incoming packet to *MiniportCoSendPackets* can be placed on the hardware immediately.

FramingBits
A 32-bit value that specifies a bitmask specifying the types of framing the miniport driver supports. The miniport driver can specify a combination of the following values, using the binary OR operator:

RAS_FRAMING
Set only if the miniport driver can detect older RAS framing. Only legacy drivers that supported earlier RAS framing set this flag.

RAS_COMPRESSION
Set only if the miniport driver supports the older RAS compression scheme.

PPP_FRAMING
Should always be set. Indicates the miniport driver can detect and support PPP framing for its medium type.

PPP_COMPRESS_ADDRESS_CONTROL
Set if the miniport driver supports PPP address and control-field compression.

NDISWAN will remove the address and control field if this LCP option is negotiated. Some WAN medium types, such as X.25, do not support this option.

PPP_COMPRESS_PROTOCOL_FIELD
Set if the miniport driver supports PPP protocol field compression.

NDISWAN will remove one byte from the protocol field when applicable if this LCP option is negotiated.

PPP_ACCM_SUPPORTED
Set if the miniport driver supports Asynchronous Control Character Mapping. This bit is only valid for asynchronous media, such as modems. If this bit is set the **DesiredACCM** member should be valid.

PPP_MULTILINK_FRAMING
Set if the miniport driver supports multiple-link framing as specified in IETF RFC 1717.

PPP_SHORT_SEQUENCE_HDR_FORMAT
Set if the miniport driver supports header format for multiple-link framing as specified in

IETF RFC 1717.

SLIP_FRAMING
Set if the miniport driver can detect and support SLIP framing (asynchronous miniport drivers only).

SLIP_VJ_COMPRESSION
Set if the miniport driver can support Van Jacobsen TCP/IP header compression for SLIP. NDISWAN supports SLIP_VJ_COMPRESSION (with 16 slots). Asynchronous media (serial miniport drivers) that support SLIP framing should set this bit.

Asynchronous media need not write any code to support VJ header compression. NDISWAN will take care of it.

SLIP_VJ_AUTODETECT
Set if the miniport driver can auto-detect Van Jacobsen TCP/IP header compression for SLIP. NDISWAN will auto-detect VJ header compression. Asynchronous media (serial miniport drivers) should set this bit if they support SLIP framing.

TAPI_PROVIDER
Set if the miniport driver supports the TAPI Service Provider OIDs. Unless this bit is set, TAPI OID calls will not be made to the miniport driver.

MEDIA_NRZ_ENCODING
Set if the miniport driver supports NRZ encoding, the PPP default for some media types such as ISDN. This value is reserved for future use.

MEDIA_NRZI_ENCODING
Set if the miniport driver supports NRZI encoding. This value is reserved for future use.

MEDIA_NLPID
Set if the miniport driver has and can set the NLPID in its frame. This value is reserved for future use.

RFC_1356_FRAMING
Set if the miniport driver supports IETF RFC 1356 X.25 and ISDN framing. This value is reserved for future use.

RFC_1483_FRAMING
Set if the miniport driver supports IETF RFC 1483 ATM adaptation layer-5 encapsulation. This value is reserved for future use.

RFC_1490_FRAMING
Set if the miniport driver supports IETF RFC 1490 Frame Relay framing. This value is reserved for future use.

NBF_PRESERVE_MAC_ADDRESS
Set if the miniport driver supports IETF framing as specified in the draft "The PPP NETBIOS Frames Control Protocol (NBFCP)."

SHIVA_FRAMING
Superseded by NBF_PRESERVE_MAC_ADDRESS.

PASS_THROUGH_MODE
Set if the miniport driver does its own framing. If this flag is set, NDISWAN passes frames, uninterpreted and unmodified.

Miniport drivers must be in the default PPP framing mode until each miniport driver receives an OID_WAN_CO_SET_LINK_INFO request. The miniport driver must auto-detect any framing that it claims to support.

For example, miniport drivers that support old RAS framing must auto-detect RAS framing from PPP framing. If a miniport driver detects a framing scheme other than the default, that miniport driver should automatically switch its framing into the newly detected framing.

A subsequent query with OID_WAN_CO_GET_LINK_INFO should indicate the detected framing. If no framing is yet detected, the **FramingBits** should be zero in the returned NDIS_WAN_CO_GET_LINK_INFO information.

If the WAN miniport driver is called subsequently with OID_WAN_CO_SET_LINK_INFO in which the **FramingBits** member is zero, the miniport driver should attempt to auto-detect the framing upon reception of each frame.

DesiredACCM
The Asynchronous Control Character Map is negotiated. This member is relevant only for asynchronous media types.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_WAN_CO_GET_LINK_INFO

OID_WAN_CO_SET_LINK_INFO

WAN_CO_LINKPARAMS

OID_WAN_CO_GET_LINK_INFO

Article • 02/18/2023

The OID_WAN_CO_GET_LINK_INFO OID requests the miniport driver to return PPP framing information about the current state of a virtual connection (VC). This information is returned in an NDIS_WAN_CO_GET_LINK_INFO structure, defined as follows.

ManagedCPlusPlus

```
typedef struct _NDIS_WAN_CO_GET_LINK_INFO {
     OUT ULONG MaxSendFrameSize;
     OUT ULONG MaxRecvFrameSize;
     OUT ULONG SendFramingBits;
     OUT ULONG RecvFramingBits;
     OUT ULONG SendCompressionBits;
     OUT ULONG RecvCompressionBits;
     OUT ULONG SendACCM;
     OUT ULONG RecvACCM;
} NDIS_WAN_CO_GET_LINK_INFO,   *PNDIS_WAN_CO_GET_LINK_INFO;
```

The members of this structure contain the following information:

MaxSendFrameSize
Specifies the maximum buffer size, in bytes, that the miniport driver can accept for transmission on this VC. The miniport driver's *MiniportCoSendPackets* function can reject any incoming send packet that is larger than this size.

MaxRecvFrameSize
Specifies the largest packet that will be received from the network. The miniport driver can drop any packets that are larger.

SendFramingBits
Specifies send-framing bits indicating the type of framing that should be sent. If the miniport driver detects incompatibilities between **SendFramingBits** and **RecvFramingBits**, it returns NDIS_STATUS_INVALID_DATA.

The proper NLPID and framing format should be used based on the framing bits wherever applicable.

RecvFramingBits
Specifies receive-framing bits indicating the type of framing that should be received.

SendCompressionBits
Reserved.

RecvCompressionBits
Reserved.

SendACCM
For asynchronous media types, logical bits 0-31 indicate the respective byte to be byte stuffed. That is, if bit 0 is set to 1, then ASCII character 0x00 should be byte stuffed, and so forth.

RecvACCM
As described for **SendACCM**.

Remarks

Possible values for **SendFramingBits** and **RecvFramingBits** include any the driver returned in response to the OID_WAN_CO_GET_LINK_INFO query.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_WAN_CO_GET_LINK_INFO

OID_WAN_CO_GET_STATS_INFO

Article • 02/18/2023

The OID_WAN_CO_GET_STATS_INFO OID requests the miniport driver to return statistics information that is specific to a virtual connection (VC). A WAN miniport driver is expected to keep statistics and to return these statistics for this OID in an NDIS_WAN_CO_GET_STATS_INFO structure, defined as follows:

ManagedCPlusPlus

```
    typedef struct _NDIS_WAN_CO_GET_STATS_INFO {
         OUT ULONG BytesSent;
         OUT ULONG BytesRcvd;
         OUT ULONG FramesSent;
         OUT ULONG FramesRcvd;
         OUT ULONG CRCErrors;
         OUT ULONG TimeoutErrors;
         OUT ULONG AlignmentErrors;
         OUT ULONG SerialOverrunErrors;
         OUT ULONG FramingErrors;
         OUT ULONG BufferOverrunErrors;
         OUT ULONG BytesTransmittedUncompressed;
         OUT ULONG BytesReceivedUncompressed;
         OUT ULONG BytesTransmittedCompressed;
         OUT ULONG BytesReceivedCompressed;
    } NDIS_WAN_CO_GET_STATS_INFO,   *PNDIS_WAN_CO_GET_STATS_INFO;
```

The members of this structure contain the following information:

BytesSent
Specifies the number of bytes transmitted.

BytesRcvd
Specifies the number of bytes received.

FramesSent
Specifies the number of frames (WAN packets) sent.

FramesRcvd
Specifies the number of frames received.

CRCErrors
Specifies the number of CRC errors encountered for this VC. CRC errors are caused by the failure of a cyclic redundancy check. A CRC error indicates that one or more bytes in the frame received were found garbled on arrival.

TimeoutErrors
Specifies the number of time-out errors encountered for this VC. Time-out errors occur when an expected byte is not received in time.

AlignmentErrors
Specifies the number of alignment errors encountered for this VC. Alignment errors occur when a byte received is different from the byte expected. This typically happens when a byte is lost or when a time-out error occurs.

SerialOverrunErrors
Specifies the number of serial overruns encountered for this VC. Serial overruns occur when the WAN NIC cannot handle the rate at which data is received.

FramingErrors
Specifies the number of framing errors encountered for this VC. A framing error occurs when an asynchronous byte is received with an invalid start or stop bit.

BufferOverrunErrors
Specifies the number of buffer overruns encountered for this VC. Buffer overruns occur when the WAN miniport driver cannot handle the rate at which data is received.

BytesTransmittedUncompressed
Specifies the number of bytes of uncompressed data transmitted. A miniport driver returns a nonzero value only if it supports compression.

BytesReceivedUncompressed
Specifies the number of bytes of uncompressed data received. A miniport driver returns a nonzero value only if it supports compression.

BytesTransmittedCompressed
Specifies the number of bytes of compressed data transmitted. A miniport driver returns a nonzero value only if it supports compression.

BytesReceivedCompressed
Specifies the number of bytes of compressed data received. A miniport driver returns a nonzero value only if it supports compression.

Remarks

If the underlying driver or its NIC does not support compression, the driver returns zero for the **Bytes..Uncompressed/Compressed** members.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_WAN_CO_SET_COMP_INFO

Article • 02/18/2023

The OID_WAN_CO_SET_COMP_INFO OID notifies the miniport driver of the PPP compression scheme selected by a protocol to which the miniport driver already returned information with a OID_WAN_CO_GET_COMP_INFO query. This PPP compression scheme is specific to a virtual connection (VC).

The protocol supplies a specification for the PPP compression scheme it selected in an NDIS_WAN_CO_SET_COMP_INFO structure, defined as follows:

ManagedCPlusPlus

```
    typedef struct _NDIS_WAN_CO_SET_COMP_INFO {
         IN NDIS_WAN_COMPRESS_INFO SendCapabilities;
         IN NDIS_WAN_COMPRESS_INFO RecvCapabilities;
    } NDIS_WAN_CO_SET_COMP_INFO,   *PNDIS_WAN_CO_SET_COMP_INFO;
```

The members of this structure contain the following information:

SendCapabilities
Specifies a structure containing information about compression capabilities for sending data.

RecvCapabilities
Specifies a structure containing information about compression capabilities for receiving data.

Remarks

For specifics of the NDIS_WAN_COMPRESS_INFO structure, see OID_WAN_GET_COMP_INFO.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_WAN_CO_GET_COMP_INFO

OID_WAN_CO_SET_LINK_INFO

Article • 02/18/2023

The OID_WAN_CO_SET_LINK_INFO OID requests the miniport driver to set PPP framing information for a specific virtual connection (VC). A protocol uses an NDIS_WAN_CO_SET_LINK_INFO structure, defined as follows, to indicate this PPP framing information.

ManagedCPlusPlus

```
    typedef struct _NDIS_WAN_CO_SET_LINK_INFO {
         IN ULONG MaxSendFrameSize;
         IN ULONG MaxRecvFrameSize;
         IN ULONG SendFramingBits;
         IN ULONG RecvFramingBits;
         IN ULONG SendCompressionBits;
         IN ULONG RecvCompressionBits;
         IN ULONG SendACCM;
         IN ULONG RecvACCM;
    } NDIS_WAN_CO_SET_LINK_INFO,   *PNDIS_WAN_CO_SET_LINK_INFO;
```

The members of this structure contain the following information:

MaxSendFrameSize
Specifies the largest buffer, in bytes, the protocol will send for this VC. This value must be less than or equal to that returned by the miniport driver for the OID_WAN_CO_GET_LINK_INFO query.

The miniport driver's *MiniportCoSendPackets* function can reject any send packets submitted for this link that are larger than this value.

MaxRecvFrameSize
Specifies the largest network packet that the protocol will receive subsequently. This value must be less than or equal to that returned by the miniport driver for the OID_WAN_CO_GET_LINK_INFO query. The miniport driver can drop any received packets for this VC that are larger.

SendFramingBits
Specifies send-framing bits indicating the type of framing that should be sent. If the miniport driver detects incompatibilities between **SendFramingBits** and **RecvFramingBits**, it returns NDIS_STATUS_INVALID_DATA.

The proper NLPID and framing format should be used based on the framing bits wherever applicable.

RecvFramingBits

Specifies receive-framing bits indicating the type of framing that should be received.

SendCompressionBits

Reserved.

RecvCompressionBits

Reserved.

SendACCM

For asynchronous media types, logical bits 0-31 indicate the respective byte to be byte stuffed. That is, if bit 0 is set to one then ASCII character 0x00 should be byte stuffed, and so forth.

RecvACCM

As described for **SendACCM**.

Remarks

Possible values for **SendFramingBits** and **RecvFramingBits** include any the underlying driver returned in response to the OID_WAN_CO_GET_INFO query.

Requirements

Version	Supported for NDIS 6.0 and NDIS 5.1 drivers in Windows Vista. Supported for NDIS 5.1 drivers in Windows XP.
Header	Ntddndis.h (include Ndis.h)

OID_WAN_CO_GET_INFO

OID_WAN_CO_GET_LINK_INFO

OID_WWAN_AUTH_CHALLENGE

Article • 02/18/2023

OID_WWAN_AUTH_CHALLENGE sends an authentication challenge to the MB device, or Subscriber Identity Module (SIM) card, to obtain the response from the SIM.

Set requests are not supported.

This is an optional OID. When miniport drivers implement it, they must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_AUTHENTICATION_RESPONSE status notification containing an NDIS_WWAN_AUTHENTICATION_RESPONSE structure to provide the authentication keys requested based on challenges by the caller when completing query requests.

Remarks

When processing this OID, miniport drivers can access the SIM card, but should not access the provider network. This OID must work even in Radio OFF or Airplane Mode.

OID_WWAN_AUTH_CHALLENGE supports both second-generation and third-generation mobile networks. SIM specifies an authentication mechanism that is based on the GSM authentication and key agreement primitives, which is a second-generation mobile network standard. AKA and AKA' uses the third-generation Authentication and Key Agreement mechanism, specified for Universal Mobile Telecommunications System (UMTS) in [TS33.102] and for CDMA2000 in [S.S0055-A] depending on the capabilities of the device.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support returning one or all authentication methods.

Requirements

Version	Supported starting with Windows 8.
Header	Ntddndis.h (include Ndis.h)

OID_WWAN_BASE_STATIONS_INFO

Article • 02/18/2023

OID_WWAN_BASE_STATIONS_INFO retrieves information about the serving and neighboring cells known to the modem. For more info about cellular base station information query, see MB base stations information query support.

For query requests, OID_WWAN_BASE_STATIONS_INFO uses the NDIS_WWAN_BASE_STATIONS_INFO_REQ structure, which in turn contains a WWAN_BASE_STATIONS_INFO structure that specifies aspects of the cell information, such as the maximum number of neighbor cell measurements, to send in response. Modem miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_BASE_STATIONS_INFO notification containing an NDIS_WWAN_BASE_STATIONS_INFO structure, which in turn contains a WWAN_BASE_STATIONS_INFO structure that provides information about both serving and neighboring base stations.

Set requests are not applicable.

Unsolicited events are not applicable.

Requirements

Version: Windows 10, version 1709 **Header**: Ntddndis.h (include Ndis.h)

MB base stations information query support

OID_WWAN_CONNECT

Article • 02/18/2023

OID_WWAN_CONNECT activates or deactivates a particular packet context and reads the activation state of a context.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_CONTEXT_STATE status notification containing an NDIS_WWAN_CONTEXT_STATE structure that indicates the Packet Data Protocol (PDP) context state of the MB device regardless of completing set or query requests.

Callers requesting to set the Packet Data Protocol (PDP) context state of the MB device provide an NDIS_WWAN_SET_CONTEXT_STATE structure to the miniport driver with the appropriate information.

Remarks

For more information about using this OID, see WWAN Packet Context Management.

This object activates or deactivates a particular packet context and reads the activation state of a context. The miniport driver must send appropriate event notifications whenever the activation state changes.

This object is called only if the miniport driver is in a register state of **WwanRegisterStateHome**, **WwanRegisterStatePartner**, or **WwanRegisterStateRoaming**. When packet service is active, the device must also be in an attach state of **WwanPacketServiceStateAttached**.

Both set and query operations are supported for this object.

- Processing of a set request requires network access but not SIM access.
- Processing of a query request does not require access to network or the SIM.

The data structure for this OID is NDIS_WWAN_SET_CONTEXT_STATE. The miniport driver issues a status indication of NDIS_STATUS_WWAN_CONTEXT_STATE for both set and query requests.

In this version of the driver model, the miniport driver attempts context activation only as instructed by the MB Service. (Miniport drivers may activate a context initiated by the network in later versions.) Miniport drivers must not automatically activate a context even after losing registration or a signal. If the access string is not provided in the activation request, a miniport driver should not attempt to provide a default string. Instead, it must proceed with activating the context with a blank access string.

On the other hand, the miniport driver may deactivate a context as instructed by the MB service. This may occur when network connectivity has been lost for a period that exceeds the threshold of temporary loss of signal, or as part of a graceful shutdown or state cleanup.

Since only one activated context is supported in this version, activating or deactivating a particular context amounts to setting up or tearing down the layer-2 MB connection.

On set requests, the MB service furnishes both **ConnectionId** and **ActivationCommand** parameters in the WWAN_CONTEXT_STATE data structure. It instructs the miniport driver to activate or deactivate a packet context identified by **ConnectionId**, based on the **ActivationCommand** parameter value *WwanActivationCommandActivate* or *WwanActivationCommandDeactivate*.

- If the service or subscription requires activation, the miniport driver should return error code WWAN_STATUS_SERVICE_NOT_ACTIVATED. The PDP-activation may not happen until the service or subscription is activated. All the emergency services might be available subject to the support from the device and the operator. The operating system might call the OID_WWAN_SERVICE_ACTIVATION in response to this error code.

- If the miniport driver receives a context activation request while another packet context is currently activated, it returns error code WWAN_STATUS_MAX_ACTIVATED_CONTEXTS.

- If the miniport driver receives a context deactivation request but the context identified by **ConnectionId** is not currently activated, it returns error code WWAN_STATUS_CONTEXT_NOT_ACTIVATED.

The miniport driver uses the following logic to determine the validity of AccessString, UserName, and Password settings from a set request:

- If **ActivationCommand** is *WwanActivationCommandDeactivate*, the miniport driver should ignore the settings of these three parameters. The rest of the cases only consider the case when **ActivationCommand** is *WwanActivationCommandActivate*.

Context activation persists across user logon and logoff. It is not per logon user.

On query requests, the MB Service uses this object to find out the activation state.

For response to query requests, miniport driver sends the NDIS_STATUS_WWAN_CONTEXT_STATE notification.

Important Note:

In rare, but specific circumstances, the MB Service on Windows 7 may attempt to auto-connect before connectivity to the Internet has been determined for pre-existing connections or during a momentary disruption in Internet connectivity of pre-existing connections. This could result in simultaneous MB and WLAN/Ethernet connections. For example, this can occur during system boot when MB and other connections are attempted simultaneously and the Network List Manager service is still attempting to determine the Internet connectivity of other connections using active and passive methods. It could also occur due to temporary outages in network infrastructure like a corporate proxy server or an ISP network. Thus, the MB Service may attempt to auto-connect to the internet regardless of whether the "Auto-connect only if no alternate Internet connection is available" option is selected.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

WWAN Packet Context Management

OID_WWAN_CREATE_MAC

Article • 02/18/2023

OID_WWAN_CREATE_MAC requests the miniport driver to create a new NDIS port. Context activation requests for the additional PDP context will be sent on this new NDIS port.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later completing the request with the **NDIS_WWAN_MAC_INFO** structure that indicates the NDIS port number and MAC address associated with the port.

Query requests are not supported.

Remarks

Miniport drivers must process requests to create (activate) new NDIS ports asynchronously in order to prevent deadlocks.

Requirements

Version	Available in Windows 8.1 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_MAC_INFO

OID_WWAN_DELETE_MAC

OID_WWAN_DELETE_MAC

Article • 02/18/2023

OID_WWAN_DELETE_MAC requests the miniport driver to delete the NDIS port specified in the NDIS_WWAN_MAC_INFO parameter. The NDIS port should have been created earlier using OID_WWAN_CREATE_MAC.

Miniport drivers must process the set request asynchronously, initially returning NDIS_STATUS_PENDING to the original request, and later completing the request with NDIS_STATUS_SUCCESS.

Query requests are not supported.

Remarks

Miniport drivers must process requests to delete (deactivate) NDIS ports asynchronously in order to prevent deadlocks.

OID_WWAN_DELETE_MAC requests sent to delete the default port will fail with the NDIS status error code NDIS_STATUS_INVALID_PORT.

Upon receiving an OID_WWAN_DELETE_MAC request, miniport drivers should deactivate the PDP context associated with the port, if it has not already been deactivated. This is because a surprise removal event could occur. Deactivating the PDP context at such time will ensure that the modem and the miniport driver remain in a good state.

When the driver receives a surprise removal, the driver blocks and cancels all further OIDs. This means that the driver filters out OID_WWAN_DELETE_MAC even though Windows sends a call with OID_WWAN_DELETE_MAC as part of the *FILTER_DETACH* call.

Requirements

Version	Available in Windows 8.1 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

OID_WWAN_CREATE_MAC

OID_WWAN_DEVICE_CAPS

Article • 02/18/2023

OID_WWAN_DEVICE_CAPS returns the capabilities of the MB device, including the cellular technology it supports, the classes of packet data it supports, the radio frequencies it supports, the type of voice service it provides, and whether it uses a Subscriber Identity Module (SIM card). The supported cellular technology and whether the device uses a SIM are particularly important because network provider selection and SIM user interfaces depend on the values of these two capabilities. The manufacturer and firmware revision are returned as optional fields.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a **NDIS_STATUS_WWAN_DEVICE_CAPS** status notification containing a **NDIS_WWAN_DEVICE_CAPS** structure that indicates the capabilities of the MB device when completing query requests.

Remarks

Starting with Windows 8, the MB driver model has been updated to version 2.0. Windows 8 miniport drivers should set the **Header.Revision** member of the **NDIS_WWAN_DEVICE_CAPS** structure to **NDIS_WWAN_DEVICE_CAPS_REVISION_2** for *query* requests. Windows 7 miniport drivers should set the **Header.Revision** member of the **NDIS_WWAN_DEVICE_CAPS** structure to **NDIS_WWAN_DEVICE_CAPS_REVISION_1** for *query* requests.

For more information about using this OID, see WWAN Driver Initialization Procedure.

Miniport drivers can access device memory when processing query operations, but should not access the provider network or the Subscriber Identity Module (SIM card).

Many "world-wide" MB devices today support multiple frequency bands because the frequency bands for 2.5G/3G vary from country to country. The list of all the radio frequencies specified in the 3GPP standards (for GSM-based networks) and 3GPP2 standards (for CDMA-based networks) is shown in the following tables. Both standards adopt a similar band classification scheme.

3GPP (GSM-based) Frequency Band Classes

3GPP band	Designated spectrum	Industry name	Uplink (MS to BTS)	Downlink (BTS to MS)	Regions
Band I	UMTS2100	IMT	1920-1980	2110-2170	Europe, Korea, Japan, China
Band II	UMTS1900	PCS1900	1850-1910	1930-1990	North America, LATAM
Band III	UMTS1800	DCS1800	1710-1785	1805-1880	Europe, China
Band IV	AWS	AWS, 1.7/2.1	1710-1755	2110-2155	North America, LATAM
Band V	UMTS850	GSM850	824-849	869-894	North America, LATAM
Band VI	UMTS800	UMTS800	830-840	875-885	Japan
Band VII	UMTS2600	UMTS2600	2500-2570	2620-2690	Europe
Band VIII	UMTS900	EGSM900	880-915	925-960	Europe, China
Band IX	UMTS1700	UMTS1700	1750-1785	1845-1880	Japan
Band X			1710-1770	2110-2170

NDIS_WWAN_DEVICE_CAPS

WWAN Driver Initialization Procedure

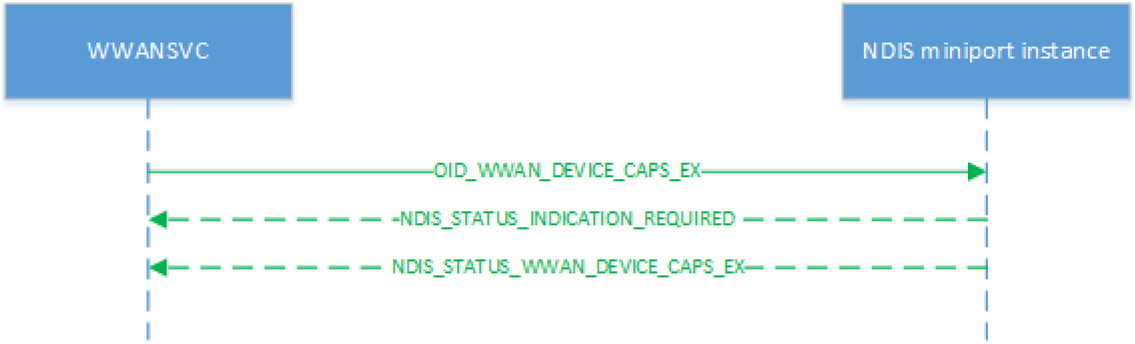
OID_WWAN_DEVICE_CAPS_EX

Article • 02/18/2023

OID_WWAN_DEVICE_CAPS_EX is similar to OID_WWAN_DEVICE_CAPS but is a per-executor OID, unlike OID_WWAN_DEVICE_CAPS which is a per-device OID. This OID serves to indicate the hardware's device/executor capability, including the capability on extended optional features such as LTE attach APN configuration.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an **NDIS_STATUS_WWAN_DEVICE_CAPS_EX** status notification containing an **NDIS_WWAN_DEVICE_CAPS_EX** structure, which in turn contains a **WWAN_DEVICE_CAPS_EX** structure, to provide information about the device's capability.

The following diagram illustrates a query request.



WWANSVC
NDIS miniport instance
OID_WWAN_DEVICE_CAPS_EX
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_DEVICE_CAPS_EX

Set requests are not applicable.

Remarks

It is critical for the driver to report service extension capability as a whole including from the driver to the actual device. If a driver supports a service but it is not supported by the underlying hardware, then the service capabilities should be marked as FALSE.

OID_WWAN_DEVICE_CAPS_EX is also used to retrieve each executor's capability. This OID is the same in structure as existing OID_WWAN_DEVICE_CAPS but with the addition of **Executor ID**. A miniport driver should report the highest OID version it supports.

Just as with OID_WWAN_DEVICE_CAPS, the parameters in this OID are not expected to change due to SIM cards but rather represent the modem's RF capability of the selected executor. A physical hardware modem may have multiple executors and thus may have multiple interfaces that support OID_WWAN_DEVICE_CAPS_EX.

For possible future updates, if the OS's requested version is newer than the device-supported version, the device should return the newest version of the OID structure it supports. If the OS's requested version is older than the latest one supported by the device, then the device should return the version matching the OS's specification. It is a requirement for IHVs to make sure all revisions of OID_WWAN_DEVICE_CAPS_EX are supported for backwards compatibility and legacy support.

Unlike other OIDs new to Windows 10 Version 1703 that are only required if the modem supports multi-SIM/multi-executors, this OID must be implemented for modems that would like to support any Microsoft-defined service extensions starting in Windows 10 Version 1703.

Versions of Windows prior to Windows 10 Version 1703 may still use the existing OID_WWAN_DEVICE_CAPS; their behavior with multi-executor capable modems is not a supported scenario. IHVs must define this behavior.

Windows 10, version 1903

Starting in Windows 10, version 1903, OID_WWAN_DEVICE_CAPS_EX has been upgraded to revision 2. A miniport driver must use revision 2 of this OID and the data structures it contains if the miniport driver supports 5G.

When the host queries capabilities using this OID, the miniport driver must check if the underlying hardware supports 5G cellular capabilities. If it does, the miniport driver sets the bitmask in the **WwanDataClass** field of the **WWAN_DEVICE_CAPS_EX** structure according to hardware capabilties.

Additionally, in the **WwanOptionalServiceCaps** field of the **WWAN_DEVICE_CAPS_EX** structure, a new optional service bit is defined that covers support of all new 5G-related extensions.

For more info about 5G data class support, see MB 5G data class support.

Requirements

Version	Windows 10, version 1703

OID_WWAN_DEVICE_RESET

Article • 02/18/2023

OID_WWAN_DEVICE_RESET is sent by the mobile broadband host to a modem miniport adapter to reset the modem device.

Query requests are not applicable.

For Set requests, OID_WWAN_DEVICE_RESET uses the NDIS_WWAN_SET_DEVICE_RESET structure. Modem miniport drivers must respond to set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_DEVICE_RESET_STATUS notification containing an NDIS_WWAN_DEVICE_RESET_STATUS structure that represents the reset status of the modem device. This response does not contain a payload, but is always a status code from the modem such as *WWAN_STATUS_SUCCESS* or *WWAN_STATUS_BUSY*.

Unsolicited events are not applicable.

Requirements

Version: Windows 10, version 1709 **Header**: Ntddndis.h (include Ndis.h)

NDIS_WWAN_DEVICE_RESET_STATUS

NDIS_WWAN_SET_DEVICE_RESET

MB modem reset operations

OID_WWAN_DEVICE_SERVICE_COMMAND

Article • 02/18/2023

OID_WWAN_DEVICE_SERVICE_COMMAND allows miniport drivers to implement vendor specific commands.

Both query and set requests are supported.

Miniport drivers must process query and set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICE_RESPONSE status notification containing a vendor-defined structure (NDIS_WWAN_DEVICE_SERVICE_COMMAND) to provide responses when they have completed the transaction.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support the specified device service or operation.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_DEVICE_SERVICE_RESPONSE

NDIS_WWAN_DEVICE_SERVICE_COMMAND

OID_WWAN_DEVICE_SERVICE_SESSION

Article • 02/18/2023

OID_WWAN_DEVICE_SERVICE_SESSION directs a miniport driver to open or close a device service session.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION status notification containing a NDIS_WWAN_SET_DEVICE_SERVICE_SESSION structure that describes the result of the operation.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support specified device service or operation.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_SET_DEVICE_SERVICE_SESSION

NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION

OID_WWAN_DEVICE_SERVICE_SESSION_WRITE

Article • 02/18/2023

OID_WWAN_DEVICE_SERVICE_SESSION_WRITE directs the miniport driver to write data to the MB device for a device service session.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE status notification containing a NDIS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE structure that describes the completion status of the operation.

Miniport drivers should return NDIS_STATUS_ADAPTER_NOT_OPEN if the device service session is not open.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE

NDIS_WWAN_DEVICE_SERVICE_SESSION_WRITE

OID_WWAN_DEVICE_SERVICES

Article • 02/18/2023

OID_WWAN_DEVICE_SERVICES returns the list of device services supported by the miniport driver.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICES status notification containing a NDIS_WWAN_DEVICE_SERVICES structure that indicates the supported device service GUIDs.

Set requests are not supported.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

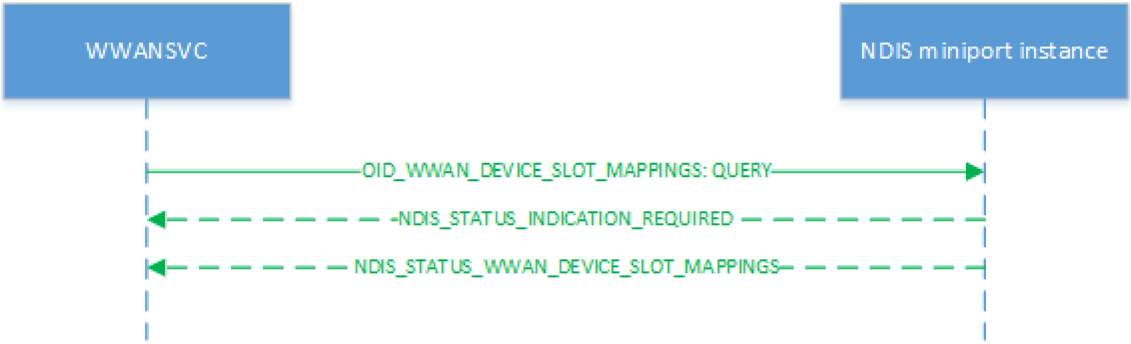
OID_WWAN_DEVICE_SLOT_MAPPING_INFO

Article • 02/18/2023

OID_WWAN_DEVICE_SLOT_MAPPING_INFO sets or returns the device-slot mappings of the MB device (i.e. the executor-slot mappings).

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPING_INFO status notification containing an NDIS_WWAN_DEVICE_SLOT_MAPPING_INFO structure to provide information on the executor-to-slot mappings.

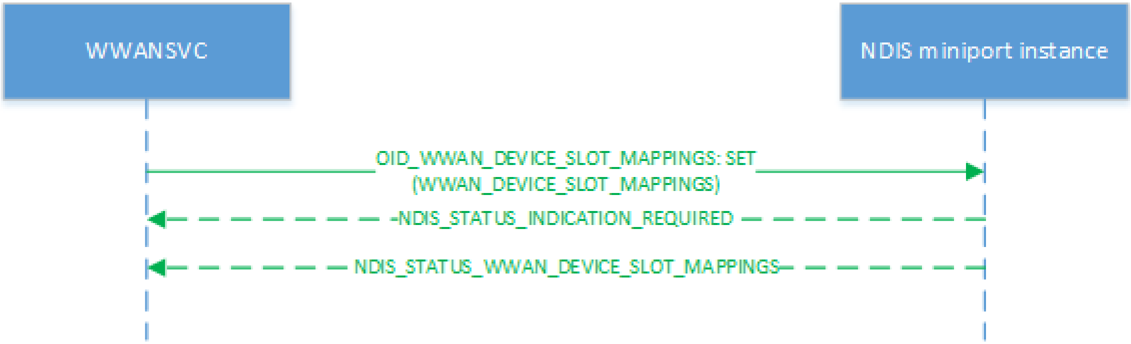
The following diagram illustrates a query request.



WWANSVC
NDIS miniport instance
OID_WWAN_DEVICE_SLOT_MAPPINGS: QUERY
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPINGS

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPING_INFO status notification containing an NDIS_WWAN_DEVICE_SLOT_MAPPING_INFO structure, which in turn contains a WWAN_DEVICE_SLOT_MAPPING_INFO structure to indicate the current mapping status. This holds true even if the set request failed. The structure for set requests for OID_WWAN_DEVICE_SLOT_MAPPING_INFO is NDIS_WWAN_SET_DEVICE_SLOT_MAPPING_INFO.

The following diagram illustrates a set request.



WWANSVC
NDIS miniport instance
OID_WWAN_DEVICE_SLOT_MAPPINGS: SET
(WWAN_DEVICE_SLOT_MAPPINGS)
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPINGS

Remarks

The host expects that on first boot, the modem would have a default mapping between slots and executors. The host performs a SET operation with OID_WWAN_DEVICE_SLOT_MAPPING_INFO to define the slot that is bound to each executor. The host expects the modem to maintain the mapping across reboots and removals/insertions. This OID is not executor-specific and may be sent to any NDIS instance on the device. It may also query the current mapping as shown above.

Requirements

Version	Windows 10, version 1703
Header	Ntddndis.h (include Ndis.h)

NDIS_WWAN_SET_DEVICE_SLOT_MAPPING_INFO

OID_WWAN_DRIVER_CAPS

Article • 02/18/2023

OID_WWAN_DRIVER_CAPS returns the version of the MB driver model supported by the miniport driver.

Set requests are not supported.

Miniport drivers process OID_WWAN_DRIVER_CAPS synchronously and should immediately return with the response buffer containing an **NDIS_WWAN_DRIVER_CAPS** structure that describes the version of the MB driver model implemented by the miniport driver when completing query requests.

Remarks

For more information about using this OID, see MB Miniport Driver Initialization.

Miniport drivers should not access the provider network, or the Subscriber Identity Module (SIM card), when processing query operations.

The current version of the MB driver model version is defined by the WWAN_MAJOR_VERSION and WWAN_MINOR_VERSION #define tokens. If the miniport driver returns a version of the MB driver model that the MB Service does not support, the MB Service will ignore the device.

When the MB Service is initialized or restarted, the miniport driver may already have been loaded. In this case, the MB Service queries the version of the MB driver model implement by miniport driver before it proceeds to issue any other OIDs. This occurs at the beginning of any session.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED in the case of any initialization error. If a miniport driver returns NDIS_STATUS_NOT_SUPPORTED, the MB Service will ignore the device and will not proceed with any other OIDs.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

OID_WWAN_ENUMERATE_DEVICE_SERVICES

Article • 02/18/2023

OID_WWAN_ENUMERATE_DEVICE_SERVICES returns the list of device services supported by the miniport driver.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICE_SUPPORTED_COMMANDS status notification containing a NDIS_WWAN_SUPPORTED_DEVICE_SERVICES structure that provides the list of supported device service GUIDs.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_DEVICE_SERVICE_SUPPORTED_COMMANDS

NDIS_WWAN_SUPPORTED_DEVICE_SERVICES

OID_WWAN_HOME_PROVIDER

Article • 02/18/2023

OID_WWAN_HOME_PROVIDER is used to set and retrieve information about the home provider of the cellular service subscription. For GSM-based devices and CDMA-based device with U-RIM, this information should be stored on the Subscriber Identity Module (SIM card). For CDMA-based devices without U-RIM, this information should be stored in auxiliary device memory.

Windows 8 supports both *set* and *query* requests. Windows 7 supports only *query* requests.

Miniport drivers must process both *set* and *query* requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request and later sending a NDIS_STATUS_WWAN_HOME_PROVIDER status notification, for a *query*, or NDIS_STATUS_WWAN_SET_HOME_PROVIDER_COMPLETE status notification, for *set*, containing an NDIS_WWAN_HOME_PROVIDER structure to return information about the home network provider with the **Provider.ProviderState** member of the NDIS_WWAN_HOME_PROVIDER structure set to WWAN_PROVIDER_STATE_HOME.

Set operations are only required to be supported by multi-carrier capable devices. The MB service will only *set* the home provider to multi-carrier providers reported by the miniport via OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS or OID_WWAN_VISIBLE_PROVIDERS. *Set* operations have an input buffer of NDIS_WWAN_SET_HOME_PROVIDER.

Remarks

A *set* operation should not require the user to unlock the device regardless if the current SIM or target SIM is in a locked state.

Current Provider SIM	Target Provider SIM	Result of *set* HOME_PROVIDER
-	Locked	Target PIN not required for setting home provider
Locked	-	Source PIN not required for setting home provider
Locked	Locked	Source and Target PIN not required for setting home provider

For more information about using this OID, see WWAN Provider Operations.

Miniport drivers can access the Subscriber Identity Module (SIM card) when processing query operations, but should not access the provider network.

Requirements

Version	Available in Windows 7 and later versions of Windows.

OID_WWAN_LTE_ATTACH_CONFIG

Article • 02/18/2023

OID_WWAN_LTE_ATTACH_CONFIG enables the operating system to query or set the default LTE attach context of the inserted SIM's provider (MCC/MNC pair).

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG status notification containing an **NDIS_WWAN_LTE_ATTACH_CONTEXTS** structure that describes the LTE attach configuration.

For Set requests, this OID's payload contains an **NDIS_WWAN_SET_LTE_ATTACH_CONTEXT** structure that describes LTE attach context information for the modem to set.

Remarks

After each Query or Set request, the miniport driver should return an NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG notification that describes the LTE attach configuration.

For more information about using this OID, see MBIM_CID_MS_LTE_ATTACH_CONFIG.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB LTE Attach Operations

NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG

NDIS_WWAN_LTE_ATTACH_CONTEXTS

NDIS_WWAN_SET_LTE_ATTACH_CONTEXT

OID_WWAN_LTE_ATTACH_STATUS

Article • 02/18/2023

OID_WWAN_LTE_ATTACH_STATUS is used to inform the OS of the last used default LTE attach context.

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_LTE_ATTACH_STATUS notification containing an **NDIS_WWAN_LTE_ATTACH_STATUS** structure that describes the last used default LTE attach context.

Set requests are not applicable.

Remarks

For more information about using this OID, see MBIM_CID_MS_LTE_ATTACH_STATUS.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB LTE Attach Operations

NDIS_STATUS_WWAN_LTE_ATTACH_STATUS

NDIS_WWAN_LTE_ATTACH_STATUS

OID_WWAN_MODEM_CONFIG_INFO

Article • 02/18/2023

OID_WWAN_MODEM_CONFIG_INFO retrieves information about the modem configuration information.

MBB drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_MODEM_CONFIG_INFO status notification containing an **NDIS_WWAN_MODEM_CONFIG_INFO** structure, which in turn contains a **WWAN_MODEM_CONFIG_INFO** structure, to provide information about the modem's configuration.

Set requests are not applicable.

Remarks

The MBB driver may not have valid information yet from the modem during early queries. The non-valid information will be set to zero.

Requirements

Version	the next major update to Windows 10
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_MODEM_CONFIG_INFO

NDIS_WWAN_MODEM_CONFIG_INFO

WWAN_MODEM_CONFIG_INFO

OID_WWAN_MODEM_LOGGING_CONFIG

Article • 02/18/2023

OID_WWAN_MODEM_LOGGING_CONFIG is used to configure logs that are collected by the modem and how often they will be sent from the modem to the host over Data Service Stream (DSS).

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_MODEM_LOGGING_CONFIG status notification containing an **NDIS_WWAN_MODEM_LOGGING_CONFIG** structure that describes the current modem logging configuration.

Set payloads contain an **NDIS_WWAN_SET_MODEM_LOGGING_CONFIG** structure specifying how to configure modem logging. Miniport drivers must process Set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_MODEM_LOGGING_CONFIG status notification containing an **NDIS_WWAN_MODEM_LOGGING_CONFIG** structure that describes the modem logging configuration after the Set request.

Remarks

Logging must be configured before a logging session is started. This is an optional OID for miniport drivers to support. However, if the miniport driver supports modem logging via the DSS channel, it must specify that it supports this OID.

For more information about usage of this OID, see MB modem logging with DSS.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

See also

MB modem logging with DSS

NDIS_WWAN_SET_MODEM_LOGGING_CONFIG

NDIS_WWAN_MODEM_LOGGING_CONFIG

OID_WWAN_MPDP

Article • 02/18/2023

OID_WWAN_MPDP sets or queries information about Multiple Packet Data Protocol (MPDP) interfaces for the MB device representing the primary PDP context/EPS bearer.

For query requests, the miniport driver responds to the MB service asynchronously by initially returning NDIS_STATUS_INDICATION_REQUIRED. After the query request is complete, the driver sends an NDIS_STATUS_WWAN_MPDP_LIST notification that contains a list of child interfaces for the primary PDP context, formatted in an **NDIS_WWAN_MPDP_LIST** structure.

For set requests, like with query requests the miniport driver responds to the MB service asynchronously by initially returning NDIS_STATUS_INDICATION_REQUIRED. The set request contains an **NDIS_WWAN_SET_MPDP_STATE** structure, which in turn contains an **NDIS_WWAN_MPDP_INFO** structure with information for the operation.

If the **Operation** member of the **NDIS_WWAN_MPDP_INFO** structure is set to **WwanMPDPOperationCreateChildInterface**, the client driver creates a new child interface for the primary PDP context. The status result of this operation, along with the GUID of the newly created child interface if the operation was successful, are returned to the MB service in an **NDIS_WWAN_MPDP_STATE** structure contained in an NDIS_STATUS_WWAN_MPDP_STATE notification.

If the **Operation** member of the **NDIS_WWAN_MPDP_INFO** structure is set to **WwanMPDPOperationDeleteChildInterface**, the miniport driver deletes the corresponding child interface it previously created and returns information about the deletion operation to the MB service in an **NDIS_WWAN_MPDP_STATE** structure contained in an NDIS_STATUS_WWAN_MPDP_STATE notification.

Requirements

Version: Windows 10, version 1809

Header: Ntddndis.h (include Ndis.h)

OID_WWAN_NETWORK_BLACKLIST

Article • 02/18/2023

ⓘ Important

Bias-free communication

Microsoft supports a diverse and inclusive environment. This article contains references to terminology that the Microsoft **style guide for bias-free communication** recognizes as exclusionary. The word or phrase is used in this article for consistency because it currently appears in the software. When the software is updated to remove the language, this article will be updated to be in alignment.

OID_WWAN_NETWORK_BLACKLIST gets or sets information about network blacklists for a mobile broadband (MBB) device.

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_NETWORK_BLACKLIST status notification containing an **NDIS_WWAN_NETWORK_BLACKLIST** structure that describes the current network blacklists.

For Set requests, this OID's payload contains an **NDIS_WWAN_SET_NETWORK_BLACKLIST** structure that specifies a list of MNC/MCC combinations that should be ignored by the modem.

Remarks

After each Query or Set request, the miniport driver should return an **NDIS_WWAN_NETWORK_BLACKLIST** structure that contains information about the current network blacklist information.

For more information about usage of this OID, see MBIM_CID_MS_NETWORK_BLACKLIST.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB Network Blacklist Operations

NDIS_STATUS_WWAN_NETWORK_BLACKLIST

NDIS_WWAN_NETWORK_BLACKLIST

NDIS_WWAN_SET_NETWORK_BLACKLIST

OID_WWAN_NETWORK_IDLE_HINT

Article • 02/18/2023

OID_WWAN_NETWORK_IDLE_HINT sends a hint to the network interface regarding whether data is expected to be active or idle on the interface. The network service uses heuristics to determine when to send this request to the interface, typically when it estimates that for a period of time there will be a reduction in network traffic or if the system is entering an idle state (such as connected standby). The network interface can use this as an input to its heuristics to implement procedures such as "fast dormancy".

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later completing the request with the NDIS_WWAN_NETWORK_IDLE_HINT structure that indicates the network idle hint.

Requirements

Version	Available in Windows 10 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_NETWORK_IDLE_HINT

OID_WWAN_NETWORK_PARAMS

Article • 02/18/2023

The host may send an OID_WWAN_NETWORK_PARAMS query request to retrieve network configuration data and/or policy information from an MB device.

Set requests are not valid.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_NETWORK_PARAMS_STATE status notification.

Remarks

For more information about usage of this OID, see MBIM_CID_MS_NETWORK_PARAMS in the MBIMEx 3.0 specification.

Requirements

Requirement	Value
Minimum supported client	Windows 11
Minimum supported server	Windows Server 2022. NDIS 6.84 and later.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_NETWORK_PARAMS_STATE

OID_WWAN_NITZ

Article • 02/18/2023

OID_WWAN_NITZ is used to query the current network time with Network Identity and Time Zone (NITZ).

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_NITZ_INFO status notification containing an **NDIS_WWAN_NITZ_INFO** structure that describes the current network time and time zone.

Set requests are not applicable.

Remarks

For more information about usage of this OID, see MB NITZ support.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

See also

MB NITZ support

NDIS_STATUS_WWAN_NITZ_INFO

NDIS_WWAN_NITZ_INFO

OID_WWAN_PACKET_SERVICE

Article • 02/18/2023

OID_WWAN_PACKET_SERVICE is used to instruct miniport drivers to perform packet service attach/detach actions on the current registered provider's network for both GSM-based and CDMA-based MB devices. In addition to the packet service attach/detach status, this OID is used to determine data class availability and the currently used data class information.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_PACKET_SERVICE** status notification containing an **NDIS_WWAN_PACKET_SERVICE_STATE** structure to provide information about the current packet service state regardless of completing set or query requests.

Callers requesting to set the current packet service state provide an **NDIS_WWAN_SET_PACKET_SERVICE** structure to the miniport driver with the appropriate information.

Remarks

See WWAN Packet Service Attach Operations for more information about using this OID.

Miniport drivers can access the provider network when processing query or set operations, but should not access the Subscriber Identity Module (SIM card).

CDMA-based devices should use this as an opportunity to release the network resource allocation if possible.

Some SIM cards enable the MB device to register only on the packet domain and not the circuit-switched domain. Once a data call ends, the VAN UI sends an OID_WWAN_PACKET_SERVICE set request to detach packet service. This causes the MB device to detach from the packet domain. The MB device unregisters from the network and goes into a power save mode. Consequently, the device disappears from the VAN UI as a result of being unregistered, and can only be recovered by rebooting. In this scenario, miniport drivers should spoof the packet attach/detach operations by returning positive data without setting the MB device into such a mode.

For technologies that do not support packet-attach, miniport drivers should spoof an attach state to let the MB Service know that it can proceed with context activation. Miniport drivers should also spoof the set OID_WWAN_PACKET_SERVICE requests in the miniport driver. Miniport drivers should send **NDIS_STATUS_WWAN_PACKET_SERVICE** notifications for query operations and for unsolicited events. Miniport drivers should fail PDP activation if the device packet service state is not set to *WwanPacketServiceStateAttached*.

The MB Service shall not proceed with context activation until the packet service state has reached *WwanPacketServiceStateAttached*.

Windows 10, version 1903

A new revision 2 for this OID is supported starting in Windows 10, version 1903. The extension enables the host to query the frequency range in which the modem is currently operating in 5G.

The host can query the extended packet service state information at any time. The response is the same as revision 1, except that revision 2 has two new fields.

If the modem is registered in a 5G domain, it returns the 5G frequency range of the carrier. If multiple 5G carriers exist, then all valid ranges are returned.

For more info about 5G data class support, see MB 5G data class support.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_SET_PACKET_SERVICE

NDIS_STATUS_WWAN_PACKET_SERVICE

WWAN Packet Service Attach Operations

OID_WWAN_PCO

Article • 02/18/2023

OID_WWAN_PCO reports the status and the payload of a Protocol Configuration Optiont (PCO) value that the modem has received from a mobile operator network. The PCO value that is returned from the modem corresponds to the PDN that the port number specifies in the OID request structure.

For query requests, the modem first responds with NDIS_STATUS_INDICATION_REQUIRED when it receives this OID. An NDIS_STATUS_WWAN_PCO_STATUS notification will be returned containing an NDIS_WWAN_PCO_STATUS structure when the query request is completed. **NDIS_WWAN_PCO_STATUS**, in turn, contains the PCO status and a WWAN_PCO_VALUE structure that represents the PCO value.

Set requests are not applicable.

Remarks

For modems that choose to use the Microsoft inbox miniport class driver, to receive query requests from the host, the modem must advertise that it supports the new **MBIM_CID_PCO** CID (index = 9) in the **MBB_UUID_BASIC_CONNECT_EXT_CONSTANT** service when responding to an **MBIM_CID_DEVICE_SERVICES** query. For more info about *MBIM_CID_PCO*, see MB Protocol Configuration Options (PCO) operations.

For modems that choose not use Microsoft inbox miniport class driver, to receive query requests from WWANSVC, the modem's miniport driver must advertise that it supports the *WWAN_OPTIONAL_SERVICE_CAPS_PCO* option when responding to OID OID_WWAN_DEVICE_CAPS_EX query requests.

Requirements

Version: Windows 10, version 1709 **Header**: Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_PCO_STATUS

WWAN_PCO_VALUE

OID OID_WWAN_DEVICE_CAPS_EX

MB Protocol Configuration Options (PCO) operations

OID_WWAN_PIN

Article • 02/18/2023

OID_WWAN_PIN sets or returns information related to Personal Identification Numbers (PINs).

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_PIN_INFO status notification when they have completed the set or query request.

Miniport drivers should send NDIS_STATUS_WWAN_PIN_INFO status notifications containing an NDIS_WWAN_PIN_INFO structure to return PIN-type and PIN-entry state information, primarily to indicate whether a PIN is required to unlock the MB device or Subscriber Identity Module (SIM card) when completing query requests.

Callers requesting to set information related to PINs provide an NDIS_WWAN_SET_PIN structure to the miniport driver to send a PIN to the MB device, enable or disable PIN settings, or to change a PIN on the SIM.

Remarks

See WWAN Pin Operations for more information about using this OID.

Windows 7 miniport drivers should use OID_WWAN_PIN. Windows 8 miniport drivers should use OID_WWAN_PIN_EX.

Miniport drivers can access the Subscriber Identity Module (SIM card) when processing query operations, but should not access the provider network.

During the miniport driver initialization process, the MB Service does not proceed to registration until PIN1 is successfully unlocked, if enabled.

Miniport drivers provide a PIN value, entered by the end user, in the **PinAction.Pin** member of the NDIS_WWAN_SET_PIN structure when processing set requests. Only when the PIN value matches the value stored in the SIM card should the request be processed by the miniport driver. Otherwise, miniport drivers should fail the set request with status code WWAN_STATUS_FAILURE.

CDMA-based devices must report the power-on device lock as PIN1.

For all supported PIN types, miniport drivers must support the *WwanPinOperationEnter* operation. Additionally, if PIN1 is supported, miniport drivers must support the

WwanPinOperationEnable, *WwanPinOperationDisable*, and *WwanPinOperationChange* operations.

If a PIN disable operation for a PIN type is tried when that PIN type is locked, miniport drivers can either fail the request with WWAN_STATUS_PIN_REQUIRED or they can successfully complete the request. If the miniport driver completes the request successfully, the disable operation should also unlock the PIN.

If reporting multiple PINs are enabled, and only one PIN can be reported at a time, then miniport drivers are expected to report PIN1 first. For example, if reporting of SubsidyLock and SIM PIN1 are enabled, then the SubsidyLock PIN should be reported (in a subsequent query request) only after PIN1 has been successfully verified.

The MB API supports other PINs in addition to PIN1. However, a 3rd-party connection manager/GUI would need to be installed because the Windows Connection Manager/GUI supports only PIN1.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

NDIS_WWAN_SET_PIN

NDIS_STATUS_WWAN_PIN_INFO

WWAN Pin Operations

OID_WWAN_PIN_EX

Article • 02/18/2023

OID_WWAN_PIN_EX sets or returns expanded information related to Personal Identification Numbers (PINs).

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_PIN_INFO status notification when they have completed the set or query request.

Miniport drivers should send NDIS_STATUS_WWAN_PIN_INFO status notifications containing an NDIS_WWAN_PIN_INFO structure to return PIN-type and PIN-entry state information, primarily to indicate whether a PIN is required to unlock the MB device or Subscriber Identity Module (SIM card) when completing query requests.

Callers requesting to set information related to PINs provide an NDIS_WWAN_SET_PIN_EX structure to the miniport driver to send a PIN to the MB device, enable or disable PIN settings, or to change a PIN on the SIM.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

OID_WWAN_PIN_EX2

Article • 02/18/2023

OID_WWAN_PIN_EX2 sets or returns expanded information related to Personal Identification Numbers (PINs). OID_WWAN_PIN_EX2 is similar to OID_WWAN_PIN_EX, but extends it to support multi-app UICC cards.

Query payloads contain an **NDIS_WWAN_PIN_APP** structure specifying the target application ID whose PIN is being queried. Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_PIN_INFO status notification containing an **NDIS_WWAN_PIN_INFO** structure that describes the PIN for the application.

Set payloads contain an **NDIS_WWAN_SET_PIN_EX2** structure specifying the PIN action to take for the application. Miniport drivers must process Set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_PIN_INFO status notification containing an **NDIS_WWAN_PIN_INFO** structure that describes the PIN state for the application.

Remarks

Only single verification-capable UICCs are supported. Multi-verification-capable UICCs that support more than one application PIN are not supported. One application PIN (PIN1) is assigned to all ADFs/DFs and files on the UICC. However, each application can specify a local PIN (PIN2) as a level 2 user verification requirement, resulting in the need for additional validation for every access command. This scenario is what OID_WWAN_PIN_EX2 supports.

Just like OID_WWAN_PIN_EX, with OID_WWAN_PIN_EX2 the device only reports one PIN at a time. If multiple PINs are enabled and reporting multiple PINs is enabled, then miniport drivers must report PIN1 first. For example, if subsidy lock reporting is enabled and the SIM's PIN1 is enabled, then the subsidy lock PIN should be reported in a subsequent query request only after PIN1 is specified by setting the **PinSize** to zero (0). In this case, a Set request is similar to a Query and returns the state of the PIN referenced. This is fully aligned to the behavior of the VERIFY command as specified in Section 11.1.9 of the ETSI TS 102 221 technical specification .

For more information about usage of this OID, see MB UICC application and file system access.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

See also

MB UICC application and file system access

NDIS_STATUS_WWAN_PIN_INFO

NDIS_WWAN_PIN_APP

NDIS_WWAN_SET_PIN_EX2

NDIS_WWAN_PIN_INFO

OID_WWAN_PIN_LIST

Article • 02/18/2023

OID_WWAN_PIN_LIST returns a list of all the different types of Personal Identification Numbers (PINs) that are supported by the MB device and additional details for each PIN type, such as the length of the PIN (minimum and maximum lengths), PIN format, PIN-entry mode (enabled/disabled/not-available). This OID also specifies the current mode of each PIN supported by the device.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_PIN_LIST** status notification containing an **NDIS_WWAN_PIN_LIST** structure to return a list of PINs with corresponding descriptions when completing query requests.

Remarks

For more information about using this OID, see WWAN Pin Operations.

Miniport drivers can access the Subscriber Identity Module (SIM card) when processing query operations, but should not access the provider network.

Miniport drivers must report all the PINs supported by their device. If the device does not support listing PINs, the miniport driver must report this list from a static (hard-coded) list maintained in the miniport driver itself for all the devices it supports.

Any PIN that provides device power-on verification or identification functionality should be reported as PIN1 and must be compliant to PIN1 guidelines.

Miniport drivers must return this information when the device ready-state changes to *WwanReadyStateInitialized* or when the device ready-state is *WwanReadyStateDeviceLocked* (PIN locked). Miniport drivers should also return this information in other device ready-states, wherever possible.

Requirements

Version	Available in Windows 7 and later versions of Windows.

NDIS_STATUS_WWAN_PIN_LIST

WWAN Pin Operations

OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS

Article • 02/18/2023

OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS is used to *set* or *query* the list of preferred multi-carrier network providers. Multi-carrier providers are ones that can be *set* as home providers.

Both *set* and *query* requests are supported. Miniport drivers must process *set* and *query* requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS status notification containing an NDIS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS structure.

Miniport drivers should set the **PreferredListHeader.ElementType** member to **WwanStructProvider2** and the **PreferredListHeader.ElementCount** member to the number of providers in the list when responding to OID_WWAN_PREFERRED_PROVIDERS *query* requests. The multi-carrier providers returned in a *query* must be able to be set as the home provider at the time the preferred multi-carrier list is returned to the service.

Miniport drivers should set the **PreferredListHeader.ElementType** member to **WwanStructProvider2** and the **PreferredListHeader.ElementCount** member to 0 when responding to OID_WWAN_PREFERRED_PROVIDERS *set* requests.

On error miniports should set the **uStatus** member of NDIS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS structure with the failure status and **PreferredListHeader.ElementCount** to 0 and **PreferredLIstHeader.ElementType** to **WwanStructProvider2**.

The **Rssi** and **ErrorRate** members of WWAN_PROVIDER2 structure should be set if available.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.

NDIS_STATUS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS

MB Provider Operations

OID_WWAN_PREFERRED_PROVIDERS

Article • 05/20/2024

OID_WWAN_PREFERRED_PROVIDERS returns information about the list of preferred providers for GSM-based devices. Miniport drivers of CDMA-based devices do not need to support this OID.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_PREFERRED_PROVIDERS status notification containing an NDIS_WWAN_PREFERRED_PROVIDERS structure to provide information about the Preferred Provider List (PPL) regardless of completing set or query requests.

Remarks

For more information about using this OID, see WWAN Provider Operations.

Miniport drivers can access the Subscriber Identity Module (SIM card) when processing query requests, but should not access the provider network.

Miniport drivers can access the Subscriber Identity Module (SIM card) or the provider network, when processing set requests.

When processing OID_WWAN_PREFERRED_PROVIDERS, miniport drivers may set only the WWAN_PROVIDER_STATE_PREFERRED or WWAN_PROVIDER_STATE_FORBIDDEN flags to tag the list entries. Be aware that forbidden providers might not appear in the list for GSM-based devices.

Miniport drivers should set the **PreferredListHeader.ElementType** member to *WwanStructProvider*. The miniport driver should set the **PreferredListHeader.ElementCount** member to 0 when responding to OID_WWAN_PREFERRED_PROVIDERS set requests.

Whether the PPL on the device can be overwritten or not when processing set requests depends on the device capability, the cellular technology, and/or the network provider's policy.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support returning or setting the PPL.

Requirements

OID_WWAN_PRESHUTDOWN

Article • 02/18/2023

OID_WWAN_PRESHUTDOWN is sent to notify the modem that the system is entering the shutdown phase and the modem should finish its operations so it can be shut down properly. It is only sent down with the port number corresponding to the physical MBB adapters. Virtual adapters that support multiple PDP contexts should not receive this OID.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning **NDIS_STATUS_INDICATION_REQUIRED** to the original request, and later sending a NDIS_STATUS_WWAN_PRESHUTDOWN_STATE status notification when the MBB driver has finished all necessary modem operations prior to shutting down. The set request has a NDIS_WWAN_SET_PRESHUTDOWN_STATE structure.

Miniport drivers should return **NDIS_STATUS_NOT_SUPPORTED** if they do not support this operation.

Requirements

Version	Available starting with Windows 10, version 1511.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_PRESHUTDOWN_STATE

NDIS_WWAN_SET_PRESHUTDOWN_STATE

OID_WWAN_PROVISIONED_CONTEXTS

Article • 02/18/2023

OID_WWAN_PROVISIONED_CONTEXTS reads or updates the provisioned context entries stored on the MB device or the Subscriber Identity Module (SIM).

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS** status notification containing an **NDIS_WWAN_PROVISIONED_CONTEXTS** structure to provide information about provisioned context entries stored on the MB device or the Subscriber Identity Module (SIM) regardless of completing set or query requests.

Remarks

For more information about using this OID, see WWAN Packet Context Management.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if the MB device they support does not support retrieval of provisioned contexts.

GSM-based devices can optionally support query and set operations. CDMA-based devices can optionally support query operations reporting Simple IP (WWAN_CTRL_CAPS_CDMA_SIMPLE_IP).

The provisioned context entries stored on the MB device or the SIM are local to the device. Miniport drivers should not connect to the network to read in these fields.

The input structure for a set request is NDIS_WWAN_SET_PROVISIONED_CONTEXT and status indication of this object is NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS.

Provisioned contexts are not same as that of the GPRS context definitions in 3GPP that caches the list of APNs. Provisioned contexts are the connectivity parameters (AccessString, UserName, and Password) that are either pre-provisioned by the Operators or OTA provisioned by the device and can be stored either in the device memory or SIM. The connectivity parameters returned by the Provisioned contexts will be used by the MB Service for PDP activation.

Both query and set form of this object is used.

Processing of this request does not require network access, but requires access to the SIM or auxiliary memory on the MB device.

The miniport driver sends NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS notification to the operating system. The **ContextListHeader.ElementType** member shall be set to *WwanStructContext*. Miniport driver should set the **ContextListHeader.ElementCount** member to 0 when notification is sent in response to a set request.

The MB Service should retrieve the list of provisioned contexts from the device before conducting any individual context activation or deactivation. The list of provisioned contexts must be restricted only to the home provider network even though the device may have the capability to store multiple network provider contexts. The context list must always be the home provider network specific even in case of roaming.

SET OID_WWAN_PROVISIONED_CONTEXT operation should associate the context with the network provider that is specified in the set request in **ProviderId** member of the WWAN_SET_CONTEXT structure. Provisioned context stored through set OID_WWAN_PROVISIONED_CONTEXT requests must persist across system restarts and device power recycles.

All the empty contexts need to be reported on a query along with the provisioned contexts applicable to the home provider network.

CDMA devices that are configured for SimpleIP, reporting in WWAN_CTRL_CAPS_CDMA_SIMPLE_IP in WwanControlCaps can optionally return at least one provisioned context filled with the correct **AccessString**, **UserName**, and **Password** members for the query request from MB Service.

Provisioned context list should be pre-provisioned in the device, updated by set OID_WWAN_PROVISIONED_CONTEXT operations, or updated by device/operator using SMS or OTA. It must not be updated dynamically based on the context information provided in the OID_WWAN_CONNECT operation by MB Service.

For more information about how to access AccessString, UserName, and Password from the MB device for each provisioned context in the list, see WWAN_CONTEXT.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

WWAN Packet Context Management

OID_WWAN_RADIO_STATE

Article • 02/18/2023

OID_WWAN_RADIO_STATE sets or returns information about a MB device's radio power state.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_RADIO_STATE status notification containing an NDIS_WWAN_RADIO_STATE structure that indicates the MB device's current radio power state regardless of completing set or query requests.

Callers requesting to set the MB device's radio power state provide an NDIS_WWAN_SET_RADIO_STATE structure to the miniport driver with the appropriate information.

Remarks

For more information about using this OID, see MB Radio State.

Miniport drivers should not access the provider network, or the Subscriber Identity Module (SIM card), when processing query or set operations.

Miniport drivers must retain software radio power states across system restart or device removal and reinsertion. Miniport drivers should store the device's software radio information and use it for setting the device software radio power state immediately on each restart or reinsertion of device. The effective radio power state of the device is decided based on combination of software and hardware radio power state as per the table in WWAN_RADIO_STATE.

If the value is *WwanRadioOn*, miniport drivers must turn on the radio power and set the **RadioState.SwRadioState** member of the WWAN_RADIO_STATE structure to *WwanRadioOn*. If the **RadioState.HwRadioState** member was *WwanRadioOff*, miniport drivers should cache this power state information and ensure to physically turn on the radio power state when **RadioState.HwRadioState** changes to *WwanRadioOn*.

If the value is *WwanRadioOff*, miniport drivers must turn off the radio power state and set the **RadioState.SwRadioState** member to *WwanRadioOff*.

Refer to the following table for the expected radio state programming by miniport drivers.

Valid Combinations for PIN Mode and PIN State

HwRadioState value	SwRadioState value	Overall radio power state
WwanRadioOff	WwanRadioOff	WwanRadioOff
WwanRadioOff	WwanRadioOn	WwanRadioOff
WwanRadioOn	WwanRadioOff	WwanRadioOff
WwanRadioOn	WwanRadioOn	WwanRadioOn

For devices that do not provide a hardware radio power switch, the **RadioState.HwRadioState** member of the NDIS_WWAN_RADIO_STATE structure must always be set to *WwanRadioOn*.

Starting in Windows 10, version 1703, OID_WWAN_RADIO_STATE has additional specifications for how a multi-executor supported modem should handle radio state configuration from the OS.

With a multi-executor supported modem, there are power benefits to configuring radio power state per executor. When an executor’s radio is turned off, the OS expects the modem to de-register from the network and does not attempt any scanning or location updates from it. The modem should support a radio state for each executor that it advertises to the OS so it can determine the hardware power state in which it should be.

As an example, if the modem has two executors and one of the executors' radio is off while the other is on, then the modem may keep the RF front end powered on to maintain registration on the executor whose radio is on but does not need to do scanning/pinging/location updates or other cellular services for the executor that is turned off. If both radios are turned off, the modem can turn off its RF front end and bring the overall hardware to a lower power state. The implementation specifics are left to each IHV.

Requirements

Version	Available in Windows 7 and later versions of Windows.

NDIS_WWAN_RADIO_STATE

NDIS_WWAN_SET_RADIO_STATE

NDIS_STATUS_WWAN_RADIO_STATE

MB Radio State

WWAN_RADIO_STATE

OID_WWAN_READY_INFO

Article • 02/18/2023

OID_WWAN_READY_INFO returns the device ready-state, which includes its Subscriber Identity Module (SIM card). This typically occurs at the beginning of any session.

Set requests are not supported.

The host can query the ready-state from either the active SIM slot or inactive SIM slot in the device if the device supports dual SIM slots. This OID's payload contains an **NDIS_WWAN_QUERY_READY_INFO** structure, which in turn contains a **WWAN_QUERY_READY_INFO** structure that specifies the UICC slot ID.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_READY_INFO** status notification containing an **NDIS_WWAN_READY_INFO** structure that indicates the MB device's ready-state when completing query requests.

Remarks

For more information about using this OID, see MB device Readiness.

Miniport drivers can access device memory or the SIM card when processing query operations, but should not access the provider network.

Miniport drivers should wait until the PIN is cleared (if required) and then read the subscriber's identity and telephone number(s) (TNs), and then set the ReadyInfo.ReadyState member of the NDIS_WWAN_READY_INFO structure to WwanReadyStateInitialized.

Miniport drivers must never fail OID_WWAN_READY_INFO and must always return the correct device ready-state.

Miniport drivers must always notify the MB Service whenever the device ready-state changes.

Miniport drivers should follow these steps to provide a good user experience:

- If PIN1 is locked, miniport drivers must first send a ready-state event notification with **ReadyInfo.ReadyState** set to *WwanReadyStateDeviceLocked*. The MB Service then sends the miniport driver an OID set request of OID_WWAN_PIN. After the device unlocks then the miniport driver must send another ready-state event notification with **ReadyInfo.ReadyState** set to *WwanReadyStateInitialized*. Until PIN1 is successfully unlocked, miniport drivers must not change the device ready-state to *WwanReadyStateInitialized*.

- Miniport drivers must first send an event notification with **ReadyInfo.ReadyState** set to *WwanReadyStateSimNotInserted* when the MB Service loads the miniport driver if no SIM card is present, as may be the case with devices that allow SIM cards to be inserted or removed. If the device has the capability to detect a hot insertion of a SIM card, the miniport driver must send another event notification with **ReadyInfo.ReadyState** set to *WwanReadyStateInitialized* when the user inserts a SIM.

- Devices that have the capability to detect service activation state must set **ReadyInfo.ReadyState** to *WwanReadyStateNotActivated*. Furthermore, if the miniport driver supports service activation, the miniport driver will receive an OID set request of OID_WWAN_SERVICE_ACTIVATION. On successful completion of service activation, miniport drivers must send another event notification with **ReadyInfo.ReadyState** set to *WwanReadyStateInitialized*.

- Miniport drivers that require a specific firmware revision must ensure that the correct firmware revision is available. If the firmware revision is not available, the miniport driver should complete the event notification transaction by setting **ReadyInfo.ReadyState** to *WwanReadyStateFailure*.

Requirements

Version: Available in Windows 7 and later versions of Windows.

WWAN_QUERY_READY_INFO

MB device Readiness

OID_WWAN_REGISTER_PARAMS

Article • 02/18/2023

OID_WWAN_REGISTER_PARAMS sets or returns the parameters that an MB device uses during 5G registration requests.

Before turning on the device radio, the host typically sends an OID_WWAN_REGISTER_PARAMS set request to configure the device with the desired registration parameters. This OID's payload contains an **NDIS_WWAN_SET_REGISTER_PARAMS** structure, which in turn contains a **WWAN_REGISTRATION_PARAMS_INFO** structure that specifies the registration parameters such as a default PDU session hint. If the device accepts these parameters, it will use them during 5G registration requests.

The host may send an OID_WWAN_REGISTER_PARAMS set request at any time. When the device receives this request, it must compare the new parameters to any parameters it previously used for 5G registration. If there are differences, the device should use the newly received parameters for the next 5G registration. The host can also use the **WWAN_REGISTRATION_PARAMS_INFO** structure's **ReRegisterIfNeeded** parameter to force immediate 5G re-registration.

The host may use this OID to query the registration parameters that an MB device is currently using for 5G registration.

Remarks

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_REGISTER_PARAMS_STATE status notification containing an **NDIS_WWAN_REGISTER_PARAMS_INFO** structure, which contains a **WWAN_REGISTRATION_PARAMS_INFO** structure.

For a failured set or query response, the information shall be null and the **InformationBufferLength** shall be zero.

In a successful set response, the **WWAN_REGISTRATION_PARAMS_INFO** structure shall contain the parameters set by the host and accepted by the device.

In a successful query response:

- If the parameters have been set by the host and accepted by the device since the device was rebooted or a different SIM was inserted, the structure shall contain the parameters set by the host and accepted by the device.

- If the parameters have not been set by the host and accepted by the device since the device was rebooted or a different SIM was inserted, the structure shall contain the parameters that the device will most likely use for 5G registration.

For more information about usage of this OID, see MBIM_CID_MS_REGISTRATION_PARAMS in the MBIMEx 3.0 specification .

Requirements

Requirement	Value
Minimum supported client	Windows 11
Minimum supported server	Windows Server 2022. NDIS 6.84 and later.
Header	Ntddndis.h (include Ndis.h)

See also

WWAN_REGISTRATION_PARAMS_INFO

NDIS_STATUS_WWAN_REGISTER_PARAMS_STATE

OID_WWAN_REGISTER_STATE

Article • 02/18/2023

OID_WWAN_REGISTER_STATE selects a network provider to register with.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_REGISTER_STATE status notification containing an NDIS_WWAN_REGISTRATION_STATE structure to provide information about the registered network provider regardless of completing set or query requests.

Callers requesting to set the network provider to register with provide an NDIS_WWAN_SET_REGISTER_STATE structure to the miniport driver with the appropriate information.

Remarks

For more information about using this OID, see WWAN Registration Operations.

Miniport drivers can access the provider network when processing query or set operations, but should not access the Subscriber Identity Module (SIM card).

The MB driver model supports two registration methods--automatic and manual. For CDMA-based networks, the MB driver model supports only automatic registration.

Devices supporting manual registration must set the **WwanControlCaps** member in WWAN_DEVICE_CAPS structure to WWAN_CTRL_CAPS_REG_MANUAL. Be aware that GSM-based devices must support manual registration.

If the registration state is automatic, miniport drivers must instruct their device to select a network provider based on the selection algorithm specific to the cellular technology and proceed with registration.

The semantics of RegisterAction values are defined as follows:

- The *WwanRegisterActionAutomatic* flag is used by the MB Service to instruct the miniport driver to set the device to automatic register mode and let the device select the best provider network. The miniport driver must ignore **ProviderId** parameter. This setting is persistent across radio states (ON/OFF), and device power cycles, until it is explicitly change by the MB Service.
- The *WwanRegisterActionManual* flag is used by the MB Service to instruct the miniport driver to register with the provider network identified by the **ProviderId**

parameter. The **ProviderId** value shall come from the **ProviderId** member of WWAN_PROVIDER data structure of one of the visible providers. This setting is persistent across radio states (ON/OFF), and device power cycles, until it is explicitly changed by the MB Service.

- Changing between the different RegisterAction values are allowed even if the device is currently registered to a provider. If the device need to deregister before switching between the Automatic and Manual registration modes, the miniport driver must ensure that the device is set to deregistration before setting to the new registration mode.
- The *Manual* and *Automatic* registration mode only affects the network selection mode. The MB device should try to register to selected network whenever the radio is turned on.

Windows 10, version 1903

A new revision 3 for this OID is supported starting in Windows 10, version 1903. This extension enables the host to query the preferred radio access technologies (RATs) from the miniport driver.

To control the preferred RAT, the host sets a bitmask representing WWAN_DATA_CLASS values in the **WwanDataClass** member of the WWAN_SET_REGISTER_STATE structure. This member represents the data access technologies that are preferred for a connection. If this field is set to **WWAN_DATA_CLASS_NONE**, then the modem should take no action for this parameter.

The host can also query the currently preferred data classes from the miniport driver. The miniport driver uses the **PreferredDataClasses** field of the WWAN_REGISTRATION_STATE structure to report the preferred data access technologies that are currently set in the modem.

For more info about 5G data class support, see MB 5G data class support.

Requirements

Version	Available in Windows 7 and later versions of Windows.

WWAN Registration Operations

OID_WWAN_SAR_CONFIG

Article • 02/18/2023

OID_WWAN_SAR_CONFIG gets or sets information about a mobile broadband (MB) device's Specific Absorption Rate (SAR) back off mode and level.

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_SAR_CONFIG status notification containing an **NDIS_WWAN_SAR_CONFIG_INFO** structure that describes the current SAR configuration.

For Set requests, this OID's payload contains an **NDIS_WWAN_SET_SAR_CONFIG** structure that specifies the new SAR configuration for the modem.

Remarks

After each Query or Set request, the miniport driver should return an **NDIS_WWAN_SAR_CONFIG_INFO** structure that contains information for all antennas on the device associated with Mobile Broadband.

For more information about usage of this OID, see MBIM_CID_MS_SAR_CONFIG.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

NDIS_WWAN_SET_SAR_CONFIG

OID_WWAN_SAR_TRANSMISSION_STATUS

Article • 02/18/2023

OID_WWAN_SAR_TRANSMISSION_STATUS enables or disables notifications from a mobile broadband (MB) modem on Specific Absorption Rate (SAR) transmission state.

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_SAR_TRANSMISSION_STATUS status notification containing an **NDIS_WWAN_SAR_TRANSMISSION_STATUS_INFO** structure that describes whether notifications on SAR transmit state are enabled in the modem.

For Set requests, this OID's payload contains an **NDIS_WWAN_SET_SAR_TRANSMISSION_STATUS** structure that specifies if SAR transmission status notifications should be enabled or disabled.

Remarks

After each Query or Set request, the miniport driver should return an **NDIS_WWAN_SAR_TRANSMISSION_STATUS_INFO** structure that describes whether SAR notifications on transmit state are enabled in the modem.

For more information about usage of this OID, see MBIM_CID_MS_TRANSMISSION_STATUS.

Requirements

NDIS_WWAN_SAR_TRANSMISSION_STATUS_INFO

NDIS_WWAN_SET_SAR_TRANSMISSION_STATUS

OID_WWAN_SERVICE_ACTIVATION

Article • 02/18/2023

OID_WWAN_SERVICE_ACTIVATION instructs miniport drivers to initiate service activation in order to gain access to the provider's network.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_SERVICE_ACTIVATION status notification containing an NDIS_WWAN_SERVICE_ACTIVATION structure to initiate service activation in order to gain access to the provider's network when they have completed the transaction.

Remarks

For more information about using this OID, see MB Service Detection and Activation.

Miniport drivers can access the Subscriber Identity Module (SIM card) or the provider network when processing query or set requests.

The MB Service uses OID_WWAN_SERVICE_ACTIVATION in the case where the service activation process requires miniport driver and user interactions.

This is not needed for miniport driver initiated or out-of-band manual service activations such as calling into the service provider's helpdesk. After the device is activated as in the above scenarios, if the current miniport driver **ReadyState** is *WwanReadyStateNotActivated*, the miniport driver shall proceed with MB initialization and notify the MB Service of ready-state change using NDIS_STATUS_WWAN_READY_INFO INDICATION .

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support miniport driver-based service activation.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

NDIS_STATUS_WWAN_SERVICE_ACTIVATION

MB Service Detection and Activation

OID_WWAN_SIGNAL_STATE

Article • 02/18/2023

OID_WWAN_SIGNAL_STATE returns or sets the current signal state.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_SIGNAL_STATE status notification containing an NDIS_WWAN_SIGNAL_STATE structure to provide information about the current signal state indication shown to the end-user regardless of completing set or query requests.

Callers requesting to set the current signal state indication to the end user provide an NDIS_WWAN_SET_SIGNAL_INDICATION structure to the miniport driver with the appropriate information.

Remarks

For more information about using this OID, see WWAN Signal Strength Operations.

Miniport drivers should not access the provider network, or the Subscriber Identity Module (SIM card), when processing query or set operations.

Generally, signal state should be indicated rather than polled. However, this OID is made available in case the current signal state needs to be determined by the MB Service.

For response to query requests, miniport drivers should send an NDIS_STATUS_WWAN_SIGNAL_STATE notification.

On a set request from the MB Service, miniport drivers should:

- Return the current values for **Rssi** and **ErrorRate** in the NDIS_WWAN_SIGNAL_STATE structure in addition to reporting the absolute values for **RssiInterval** and **RssiThreshold** that has been set in the miniport driver.

- Internally cache the **RssiInterval** and/or **RssiThreshold** values even if the device is not currently registered with any operator and that any restriction imposed by device in setting parameters can only be possible post-registration state. The miniport driver should try to apply these settings in the next immediate available situation.

- Complete the request successfully, if the hardware and/or software radio switch state is currently OFF. Miniport driver cache the request data and start reporting the signal strength after the switch is turned ON.

- Can fail this request with the appropriate **uStatus** error code set.

Miniport drivers can do the following when processing query requests from the MB Service:

- Return the current values for **Rssi** and **ErrorRate** in the NDIS_WWAN_SIGNAL_STATE structure in addition to reporting the absolute values for **RssiInterval** and **RssiThreshold** that has been set in the miniport driver.

- Fail this request with the appropriate **uStatus** error code set.

Return Values:

NDIS_STATUS_NOT_SUPPORTED

Miniport drivers can return this for specific devices that are aware of device capabilities not supporting the signal strength can fail the request with this error code.

Recommended Implementation

1. Devices must support signal strength indications.

2. Drivers must report signal strength indications of at least 50% of the **RssiInterval** setting over a time period of five minutes.

3. Devices must avoid reporting the signal strength in the following states:

   a. Device not registered or deregistered and is applicable only for GSM devices.

   b. Effective state of radio is OFF.

   c. In the above states, a query to the signal strength must be returned with the following data by the miniport driver:

      Rssi = WWAN_RSSI_UNKNOWN

      ErrorRate = WWAN_ERROR_RATE_UNKNOWN;

      RssiInterval = < WWAN_RSSI_DISABLE, WWAN_RSSI_DEFAULT or last set value>

      RssiThreshold = < WWAN_RSSI_DISABLE, WWAN_RSSI_DEFAULT or the last set value>

Windows 10, version 1903

Starting in Windows 10, version 1903, OID_WWAN_SIGNAL_STATE has been upgraded to revision 3. This revision enables the host to query new reference signal received power

(RSRP) and Signal-to-Noise (SNR) values from the miniport driver. A miniport driver must use revision 3 of this OID and its data structures if the driver supports 5G.

For more info about 5G data class support, see MB 5G data class support.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_SET_SIGNAL_INDICATION

WWAN Signal Strength Operations

OID_WWAN_SLOT_INFO

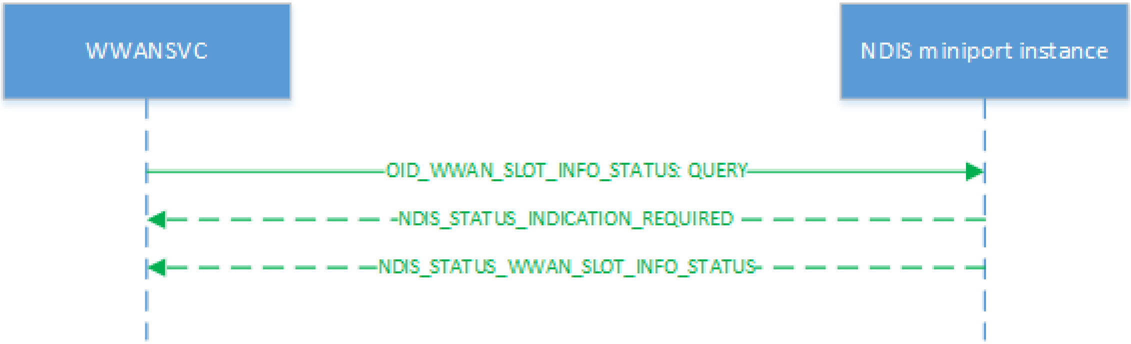
Article • 02/18/2023

OID_WWAN_SLOT_INFO retrieves a high-level aggregated status of a specified UICC slot and the card within it (if any). It may also be used to deliver an unsolicited notification when the status of one of the slots changes.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_SLOT_INFO status notification containing an NDIS_WWAN_SLOT_INFO structure, which in turn contains a WWAN_SLOT_INFO structure, to provide information about the overall modem system capability.

Query requests specify NDIS_WWAN_GET_SLOT_INFO structure as input. The miniport driver should return the slot status according to the slot ID specified in the **SlotIndex** member of the WWAN_GET_SLOT_INFO structure.

The following diagram illustrates a query request.



WWANSVC
NDIS miniport instance
OID_WWAN_SLOT_INFO_STATUS: QUERY
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_SLOT_INFO_STATUS

Set requests are not applicable.

An NDIS_STATUS_WWAN_SLOT_INFO notification with a NDIS_WWAN_SLOT_INFO structure is sent to host when the slot/card state changes.

Remarks

The host uses OID_WWAN_SLOT_INFO to query the status of a specific slot on the modem. This OID is not executor-specific and may be sent to any NDIS instance belonging to one modem. The slot state represents a summary of both the slot and card state.

The set of reported states is constrained by the capability of the slot hardware. In the most restrictive case, the slot hardware may only be able to determine that a card is present when it is powered on and active—in such a case the **OffEmpty** and **Off** states will not be reported.

OID_WWAN_READY_INFO and OID_WWAN_SLOT_INFO perform the same core function of retrieving the device ready-state of a SIM card slot; however, OID_WWAN_READY_INFO is a per-executor command whereas OID_WWAN_SLOT_INFO could be used on any physical instance (executor) and is expected to return the appropriate slot state even if it is not mapped to any executors at the moment.

Requirements

Version	Windows 10, version 1703

OID_WWAN_SMS_CONFIGURATION

Article • 02/18/2023

OID_WWAN_SMS_CONFIGURATION sets or returns a MB device's SMS text message configuration.

Miniport drivers must process set and query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_SMS_CONFIGURATION status notification regardless of completing set or query requests.

Query requests return the MB device's current SMS text message configuration stored in the device or Subscriber Identity Module (SIM) card.

Set requests use the NDIS_WWAN_SET_SMS_CONFIGURATION structure to change the SMS text message configuration of the MB device.

Remarks

For more information about using this OID, see WWAN SMS Operations.

When processing this OID, miniport drivers can access the SIM card, but should not access the provider network.

Miniport drivers of GSM-based devices should support both query and set operations. Miniport drivers of CDMA-based devices should support only query operations. Miniport drivers of CDMA-based devices should return a valid value in the **ulMaxMessageIndex** member of the WWAN_SMS_CONFIGURATION structure for query requests and can ignore the other members.

Miniport drivers must send an unsolicited NDIS_STATUS_WWAN_SMS_CONFIGURATION indication when the MB device's SMS subsystem is ready for SMS operation. Thereafter, when responding to OID_WWAN_SMS_CONFIGURATION query requests, miniport drivers must return valid values for all members of the WWAN_SMS_CONFIGURATION structure.

Miniport drivers should return NDIS_STATUS_NOT_INITIALIZED if the device is initialized but the SMS subsystem is not yet initialized.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support configuring SMS text messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.

OID_WWAN_SMS_DELETE

Article • 02/18/2023

OID_WWAN_SMS_DELETE deletes SMS text messages stored in the MB device, or Subscriber Identity Module (SIM card), or any other auxiliary non-volatile memory or memories.

Query requests are not supported.

Set requests use the NDIS_WWAN_SMS_DELETE structure.

Miniport drivers process this OID asynchronously, and should return an NDIS_STATUS_INDICATION_REQUIRED provisional response to any set requests. Miniport drivers should send an NDIS_STATUS_WWAN_SMS_DELETE indication when they have completed the transaction.

Remarks

For more information about using this OID, see WWAN SMS Operations.

When processing this OID, miniport drivers can access the Subscriber Identity Module (SIM card), but should not access the provider's network.

Miniport drivers may receive requests to delete SMS text messages based on an index, or to delete all SMS text messages. Delete requests may consist of any one of the basic filters such as new (unread) messages, old (read) messages, draft messages, or sent messages.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support SMS text messages, or the ability to delete SMS text messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

OID_WWAN_SMS_READ

Article • 02/18/2023

OID_WWAN_SMS_READ reads SMS text messages stored in the MB device, or Subscriber Identity Module (SIM card), or any other auxiliary non-volatile memory or memories.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_SMS_RECEIVE** status notification containing an **NDIS_WWAN_SMS_READ** structure to provide the SMS messages requested that was initially provided by the caller when completing query requests.

Callers requesting to read SMS text messages provide an NDIS_WWAN_SMS_READ structure to indicate which SMS messages the caller wants the miniport to return.

Remarks

For more information about using this OID, see WWAN SMS Operations.

When processing this OID, miniport drivers can access the Subscriber Identity Module (SIM card), but should not access the provider network.

OID_WWAN_SMS_READ supports reading both PDU-mode and CDMA-mode SMS text messages, depending on the capabilities of the device.

Miniport drivers may receive requests to read SMS text messages based on an index, or to read all SMS text messages. Read requests may consist of any one of the basic filters such as new (unread) messages, old (read) messages, draft messages, or sent messages.

Miniport drivers that implement SMS text message functionality must support the reading of new messages using the basic filter for *WwanSmsFlagNew*. All other filter types are optional to support.

Miniport drivers must logically project a single SMS text message store across all available physically different SMS text message stores.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support SMS text messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_SMS_READ

WWAN SMS Operations

OID_WWAN_SMS_SEND

Article • 02/18/2023

OID_WWAN_SMS_SEND sends SMS text messages to another MB device.

Query requests are not supported.

Set requests use the NDIS_WWAN_SMS_SEND structure.

Miniport drivers process this OID asynchronously, and should return an NDIS_STATUS_INDICATION_REQUIRED provisional response to any set requests. Miniport drivers should send an NDIS_STATUS_WWAN_SMS_SEND indication when they have completed the transaction.

Remarks

For more information about using this OID, see WWAN SMS Operations.

When processing this OID, miniport drivers can access the provider network, but should not access the Subscriber Identity Module (SIM card).

OID_WWAN_SMS_SEND supports sending both PDU-mode and CDMA-mode SMS text messages, depending on the capabilities of the device.

GSM-based devices are expected to support only PDU-mode SMS text messages. CDMA-based devices are expected to support only CDMA-mode SMS text messages. Miniport drivers must be able to complete set requests irrespective of SMS text message mode.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support SMS text messages, or the ability to send SMS text messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_WWAN_SMS_SEND

WWAN SMS Operations

OID_WWAN_SMS_STATUS

Article • 02/18/2023

OID_WWAN_SMS_STATUS reports the status of the MB device's message store.

Set requests are not supported.

Query requests do not use a structure.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an **NDIS_STATUS_WWAN_SMS_STATUS** status notification that indicates the status of the MB device's message store when completing query requests.

Remarks

For more information about using this OID, see WWAN SMS Operations.

When processing this OID, miniport drivers can access the Subscriber Identity Module (SIM card), but should not access the provider network.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support SMS text messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

WWAN SMS Operations

NDIS_STATUS_WWAN_SMS_STATUS

OID_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS

Article • 02/18/2023

OID_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS sets information about the list of device services for which the MB device must send NDIS_STATUS_WWAN_DEVICE_SERVICE_EVENT notifications. The MB device should not indicate events for any device service which is not in this list.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a NDIS_STATUS_WWAN_DEVICE_SERVICE_SUBSCRIPTION status notification that contains the current list of event subscriptions on the MB device.

Callers requesting to set the MB device service event subscription list provide a NDIS_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS structure to the miniport driver with the appropriate information.

Requirements

Version	Versions: Supported in Windows 8 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_DEVICE_SERVICE_EVENT

NDIS_STATUS_WWAN_DEVICE_SERVICE_SUBSCRIPTION

NDIS_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS

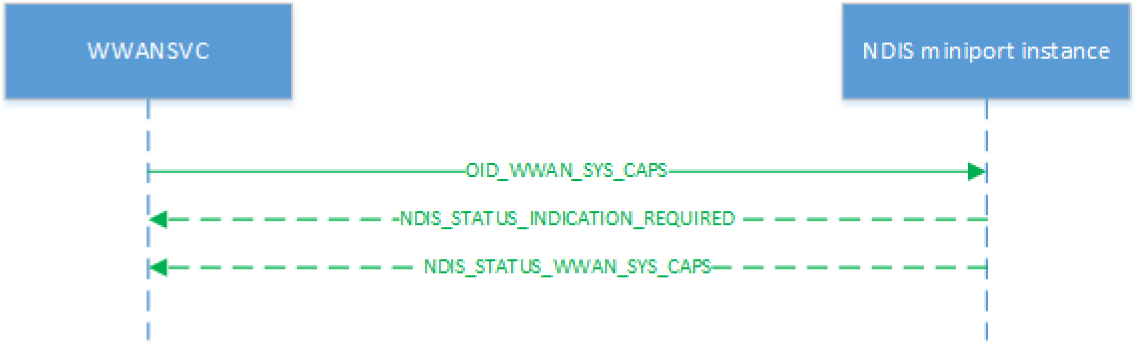
OID_WWAN_SYS_CAPS_INFO

Article • 02/18/2023

OID_WWAN_SYS_CAPS_INFO retrieves information about the modem. It can be sent on any of the NDIS instances exposed by the modem.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_SYS_CAPS_INFO status notification containing an NDIS_WWAN_SYS_CAPS_INFO structure, which in turn contains a WWAN_SYS_CAPS_INFO structure, to provide information about the overall modem system capability.

The following diagram illustrates a query request.



Set requests are not applicable.

Remarks

The host uses OID_WWAN_SYS_CAPS_INFO to query the number of devices (executors) and slots in the modem as well as the number of executors that may be active concurrently. A dual-standby modem would have a concurrency of 1; a dual-active modem would have a concurrency of 2. This OID is not executor-specific and may be sent to any NDIS instance.

The modem may expose multiple configurations with differing numbers of executors and slots. Regardless of which configuration is selected, this query will return the maximum number of devices and slots that the modem can support as currently configured.

A modem supporting OID_WWAN_SYS_CAPS_INFO is expected to also support OID_WWAN_DEVICE_CAPS_EX. Versions of Windows that support multi-executor modems will not use the legacy OID_WWAN_DEVICE_CAPS if the underlying modem supports OID_WWAN_SYS_CAPS_INFO. For legacy versions of the OS (any version before Windows 10 Version 1703 for the purposes of this OID), a multi-executor modem would be represented as multiple independent modems and the existing OID_WWAN_DEVICE_CAPS, available starting in Windows 8, will be used.

Requirements

Version	Windows 10, version 1703
Header	Ntddndis.h (include Ndis.h)

See also

OID_WWAN_DEVICE_CAPS

OID_WWAN_UE_POLICY

Article • 02/18/2023

OID_WWAN_UE_POLICY returns the UE policies from an MB device.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_UE_POLICY_STATE status notification containing an **NDIS_WWAN_UE_POLICY_INFO** structure that indicates the MB device's UE policies when completing query requests.

Miniport drivers can also send unsolicited events with this notification.

Requirements

Version: Windows 11, version 21H2

Header: Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_UE_POLICY_STATE

NDIS_WWAN_UE_POLICY_INFO

OID_WWAN_UICC_ACCESS_BINARY

Article • 02/18/2023

OID_WWAN_UICC_ACCESS_BINARY accesses a UICC binary file, the structure type of which is **WwanUiccFileStructureTransparent** or **WwanUiccFileStructureBerTLV**.

Query requests read a binary file. Query payloads contain an **NDIS_WWAN_UICC_ACCESS_BINARY** structure specifying information about the file to read. Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_BINARY_RESPONSE status notification containing an **NDIS_WWAN_UICC_RESPONSE** structure that describes the UICC's response.

Remarks

For more information about usage of this OID, see MB UICC application and file system access.

Requirements

OID_WWAN_UICC_ACCESS_RECORD

Article • 02/18/2023

OID_WWAN_UICC_ACCESS_RECORD accesses a UICC linear fixed or cyclic file, the structure type of which is **WwanUiccFileStructureCyclic** or **WwanUiccFileStructureLinear**.

Query requests read the contents of a record. Query payloads contain an **NDIS_WWAN_UICC_ACCESS_RECORD** structure specifying information about the file to read. Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_RECORD_RESPONSE status notification containing an **NDIS_WWAN_UICC_RESPONSE** structure that describes the UICC's response.

Remarks

For more information about usage of this OID, see MB UICC application and file system access.

OID_WWAN_UICC_APP_LIST

Article • 02/18/2023

OID_WWAN_UICC_APP_LIST retrieves a list of applications in a UICC and information about them.

Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_UICC_APP_LIST status notification containing an **NDIS_WWAN_UICC_APP_LIST** structure that describes the app list for the UICC.

Set requests are not applicable.

Remarks

When the UICC in the modem is fully initialized and ready to register with the mobile operator, a UICC application must be selected for registration and a Query request with this OID should return the selected application in the **ActiveAppIndex** field of the **WWAN_UICC_APP_LIST** structure used in response.

For more information about usage of this OID, see MB UICC application and file system access.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

OID_WWAN_UICC_ATR

Article • 02/18/2023

An OID_WWAN_UICC_ATR query request is sent by the mobile broadband host to a modem miniport adapter to get the UICC smart card's Answer to Reset (ATR) information. The ATR is the first string of bytes sent by the UICC after a reset has been performed. It describes the capabilities of the card, such as the number of logical channels that it supports.

The host can query the ATR information from either the active SIM slot or the inactive SIM slot in the device if the device supports dual SIM slots. This OID's payload contains an **NDIS_WWAN_QUERY_ATR_INFO** structure, which in turn contains a **WWAN_QUERY_ATR_INFO** structure that specifies the UICC slot ID.

Modem miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_ATR_INFO notification containing a **NDIS_WWAN_ATR_INFO** structure, which in turn contains a **WWAN_QUERY_ATR_INFO** structure that represents the passthrough status of the adapter.

Unsolicited events are not applicable.

For more info, see MB low level UICC access.

Requirements

Version: Windows 10, version 1607

OID_WWAN_UICC_FILE_STATUS

Article • 02/18/2023

OID_WWAN_UICC_FILE_STATUS retrieves information about a specified UICC file.

Query payloads contain an **NDIS_WWAN_UICC_FILE_PATH** structure containing information about the target file. Miniport drivers must process Query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_FILE_STATUS status notification containing an **NDIS_WWAN_UICC_FILE_STATUS** structure that describes the specified file.

Set requests are not applicable.

Remarks

For more information about usage of this OID, see MB UICC application and file system access.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

NDIS_WWAN_UICC_FILE_STATUS

OID_WWAN_UICC_RESET

Article • 02/18/2023

OID_WWAN_UICC_RESET is sent by the mobile broadband host to a modem miniport adapter to reset a UICC smart card and specify the UICC's passthrough status after reset, or query the passthrough state of the adapter.

The host can query the passthrough state from either the active SIM slot or inactive SIM slot in the device if the device supports dual SIM slots. This OID's payload for query requests contains an **NDIS_WWAN_QUERY_UICC_RESET** structure, which in turn contains a **WWAN_QUERY_UICC_RESET** structure that specifies the UICC slot ID.

Modem miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_RESET_INFO notification containing a **NDIS_WWAN_UICC_RESET_INFO** structure, which in turn contains a **WWAN_UICC_RESET_INFO** structure that represents the passthrough status of the adapter.

The host can reset either the active SIM slot or inactive SIM slot in the device if the device supports dual SIM slots. For set requests, OID_WWAN_UICC_RESET uses the **NDIS_WWAN_SET_UICC_RESET** structure, which in turn contains a **WWAN_SET_UICC_RESET** structure that represents the passthrough action the host specifies for the miniport adapter after it resets the UICC. After reset is complete, the miniport adapter responds with the NDIS_STATUS_WWAN_UICC_RESET_INFO notification, which in turn contains a **NDIS_WWAN_UICC_RESET_INFO** structure, to indicate its passthrough status.

Unsolicited events are not applicable.

For more info about passthrough actions and passthrough status, see MB low level UICC access.

OID_WWAN_UICC_TERMINAL_CAPABILITY

Article • 02/18/2023

The mobile broadband host sends OID_WWAN_UICC_TERMINAL_CAPABILITY to a modem miniport adapter to inform the modem about the terminal capabilities of the host.

If the device supports dual SIM slots, the host can set terminal capability on either the active or inactive SIM slot to inform the modem of the host OS's capabilities. The host can also query the terminal capability that persisted in the modem from a previous SIM insertion/reset.

For query requests, this OID's payload contains an **NDIS_WWAN_QUERY_UICC_TERMINAL_CAPABILITY** structure, which in turn contains a **WWAN_QUERY_UICC_TERMINAL_CAPABILITY** structure that specifies the slot ID. Modem miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request before later sending an NDIS_STATUS_WWAN_UICC_TERMINAL_CAPABILITY_INFO notification containing an **NDIS_WWAN_UICC_TERMINAL_CAPABILITY_INFO** structure, which in turn contains a **WWAN_UICC_TERMINAL_CAPABILITY_INFO** structure that represents the terminal capabilities.

For set requests, OID_WWAN_UICC_TERMINAL_CAPABILITY uses the **NDIS_WWAN_SET_UICC_TERMINAL_CAPABILITY** structure, which in turn contains a **WWAN_SET_UICC_TERMINAL_CAPABILITY** structure that represents the terminal capabilities and specifies the slot ID. The miniport driver responds with the NDIS_STATUS_WWAN_UICC_TERMINAL_CAPABILITY_INFO notification, which in turn contains an **NDIS_WWAN_UICC_TERMINAL_CAPABILITY_INFO** structure.

Unsolicited events are not applicable.

For more information, see MB low level UICC access.

Requirements

OID_WWAN_USSD

Article • 02/18/2023

OID_WWAN_USSD sends Unstructured Supplementary Service Data (USSD) requests to the underlying MB device.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_USSD status notification containing the status of the initial USSD request when they have completed the transaction.

Windows does not send an OID_WWAN_USSD request to a miniport driver if a previous request is still in progress, with the exception of a request to cancel a pending operation by setting the WWAN_USSD_REQUEST **RequestType** member of the request to *WwanUssdRequestCancel*.

When a request is canceled, the miniport driver must respond to both the canceled request and the cancel request.

Requirements

Version	Supported starting with Windows 8.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_USSD

WWAN_USSD_REQUEST

OID_WWAN_VENDOR_SPECIFIC

Article • 02/18/2023

OID_WWAN_VENDOR_SPECIFIC allows miniport drivers to implement vendor specific objects.

Query requests are not supported.

Miniport drivers must process set requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending a **NDIS_STATUS_WWAN_VENDOR_SPECIFIC** status notification containing a vendor-defined structure to implement private objects when they have completed the transaction.

Remarks

For more information about using this OID, see WWAN Vendor Specific Operations.

Miniport drivers should return NDIS_STATUS_NOT_SUPPORTED if they do not support vendor-specific operations.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

WWAN Vendor Specific Operations

NDIS_STATUS_WWAN_VENDOR_SPECIFIC

OID_WWAN_VISIBLE_PROVIDERS

Article • 02/18/2023

OID_WWAN_VISIBLE_PROVIDERS returns a list of network providers currently visible within the MB device's range.

Set requests are not supported.

Miniport drivers must process query requests asynchronously, initially returning NDIS_STATUS_INDICATION_REQUIRED to the original request, and later sending an NDIS_STATUS_WWAN_VISIBLE_PROVIDERS status notification containing an NDIS_WWAN_VISIBLE_PROVIDERS structure to provide information about visible network providers when completing query requests.

Query requests specify NDIS_WWAN_GET_VISIBLE_PROVIDERS structure as input. When the **Action** member in WWAN_GET_VISIBLE_PROVIDERS is set to WWAN_GET_VISIBLE_PROVIDERS_ALL the miniport should return all visible providers. When the **Action** member in WWAN_GET_VISIBLE_PROVIDERS is set to WWAN_GET_VISIBLE_PROVIDERS_MULTICARRIER the miniport should only return visible multi-carrier providers that can be set as the home provider.

The visible provider list returned by the device should have the provider state set correctly for each of the providers. For example, the multicarrier preferred providers should be tagged as WWAN_PROVIDER_STATE_PREFERRED_MULTICARRIER, the current home provider if any should be tagged as WWAN_PROVIDER_STATE_HOME, The current registered provider if any should be tagged as WWAN_PROVIDER_STATE_REGISTERED.

The **Rssi** and **ErrorRate** members of WWAN_PROVIDER2 structure should be set if available.

Remarks

For more information about using this OID, see WWAN Provider Operations.

Miniport drivers can access the Subscriber Identity Module (SIM card) when processing query operations, but should not access the provider network.

Miniport drivers should set the **VisibleListHeader.ElementType** member to *WwanStructProvider*.

For CDMA-based networks, miniport driver should return only the home provider, if any of the networks in the Preferred Roaming List (PRL) is currently visible. For GSM-based networks, more than one provider may be present in the visible provider list.

Devices that do not support scanning for visible providers while connected should return the WWAN_STATUS_BUSY error value in the **uStatus** member of the NDIS_WWAN_VISIBLE_PROVIDERS structure.

Both GSM-based and CDMA-based devices must support scanning for visible providers while in registered mode. However, miniport drivers are not required to support scanning for visible provider while a Packet Data Protocol (PDP) context is active (for example, the device is connected to the provider's network).

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ntddndis.h (include Ndis.h)

See also

NDIS_STATUS_WWAN_VISIBLE_PROVIDERS

WWAN Provider Operations

Ws2def.h

Article • 12/15/2021

This section contains kernel mode network driver topics for the Ws2def.h header. This header is included in the Windows SDK as it is also shared with user mode networking applications.

The Ws2def.h header contains definitions for the Winsock2 specification. It is included in Winsock2.h. User mode applications should include Winsock2.h rather than including Ws2def.h directly. Ws2def.h cannot be included by a module that also includes Winsock.h.

> ⓘ **Important**
>
> This section's topics contains pages for definitions, macros, OIDs, status indications, and other data structures that are not part of network driver reference (structures, enumerations, functions, and callbacks).
>
> For more information about network driver reference for this header, see **Ws2def.h (reference)**.

AF_INET

Article • 03/03/2023

The AF_INET address family is the address family for IPv4.

Socket Address Structure

An IPv4 transport address is specified with the SOCKADDR_IN structure.

Socket Types

IPv4 supports the following socket types:

SOCK_STREAM
Supports reliable connection-oriented byte stream communication.

SOCK_DGRAM
Supports unreliable connectionless datagram communication.

SOCK_RAW
Supports raw access to the transport protocol.

A WSK application specifies a socket type when it calls the WskSocket function or the WskSocketConnect function to create a new socket.

Protocols

The following IPv4 IPPROTO_*XXX* protocol values of the IPPROTO enumeration are defined in the WSK header files:

IPPROTO_IP
Internet protocol options

IPPROTO_ICMP
Internet control message protocol

IPPROTO_IGMP
Internet group management protocol

IPPROTO_GGP
Gateway to gateway protocol

IPPROTO_IPV4

IPv4 encapsulation

IPPROTO_ST

Stream protocol

IPPROTO_TCP

Transmission control protocol

IPPROTO_CBT

Core based trees protocol

IPPROTO_EGP

Exterior gateway protocol

IPPROTO_IGP

Private interior gateway protocol

IPPROTO_PUP

PARC universal packet protocol

IPPROTO_UDP

User datagram protocol

IPPROTO_IDP

Internet datagram protocol

IPPROTO_RDP

Reliable data protocol

IPPROTO_ND

Net disk protocol

IPPROTO_ICLFXBM

Wideband monitoring

IPPROTO_PIM

Protocol independent multicast

IPPROTO_PGM

Pragmatic general multicast

IPPROTO_L2TP

Level 2 tunneling protocol

IPPROTO_SCTP
Stream control transmission protocol

IPPROTO_RAW
Raw IP packets

Additional protocols are supported through the use of raw sockets.

A WSK application specifies a protocol when it calls the **WskSocket** function or the **WskSocketConnect** function to create a new socket.

A WSK application also specifies a protocol (as the *Level* parameter) when it calls the **WskControlSocket** function to set or retrieve transport protocol level or network protocol level socket options.

Combinations

IPv4 supports the following combinations of socket types and protocols for each WSK socket category:

Basic Sockets SOCK_STREAM + IPPROTO_TCP SOCK_DGRAM + IPPROTO_UDP SOCK_RAW + IPPROTO_*Xxx* Listening Sockets SOCK_STREAM + IPPROTO_TCP

Datagram Sockets SOCK_DGRAM + IPPROTO_UDP SOCK_RAW + IPPROTO_*Xxx* Connection-Oriented Sockets SOCK_STREAM + IPPROTO_TCP

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

AF_INET6

Article • 03/03/2023

The AF_INET6 address family is the address family for IPv6.

Socket Address Structure

An IPv6 transport address is specified with the SOCKADDR_IN6 structure.

Socket Types

IPv6 supports the following socket types:

SOCK_STREAM
Supports reliable connection-oriented byte stream communication.

SOCK_DGRAM
Supports unreliable connectionless datagram communication.

SOCK_RAW
Supports raw access to the transport protocol.

A WSK application specifies a socket type when it calls the WskSocket function or the WskSocketConnect function to create a new socket.

Protocols

The following IPv6 IPPROTO_*XXX* protocol values of the IPPROTO enumeration are defined in the WSK header files:

IPPROTO_HOPOPTS
IPv6 hop-by-hop options

IPPROTO_ICMP
Internet control message protocol

IPPROTO_IGMP
Internet group management protocol

IPPROTO_GGP
Gateway to gateway protocol

IPPROTO_IPV4

IPv4 encapsulation

IPPROTO_ST

Stream protocol

IPPROTO_TCP

Transmission control protocol

IPPROTO_CBT

Core based trees protocol

IPPROTO_EGP

Exterior gateway protocol

IPPROTO_IGP

Private interior gateway protocol

IPPROTO_PUP

PARC universal packet protocol

IPPROTO_UDP

User datagram protocol

IPPROTO_IDP

Internet datagram protocol

IPPROTO_RDP

Reliable data protocol

IPPROTO_IPV6

IPv6 header

IPPROTO_ROUTING

IPv6 routing header

IPPROTO_FRAGMENT

IPv6 fragmentation header

IPPROTO_ESP

Encapsulating security payload

IPPROTO_AH

Authentication header

IPPROTO_ICMPV6

IPv6 Internet control message protocol

IPPROTO_NONE

IPv6 no next header

IPPROTO_DSTOPTS

IPv6 destination options

IPPROTO_ND

Net disk protocol

IPPROTO_ICLFXBM

Wideband monitoring

IPPROTO_PIM

Protocol independent multicast

IPPROTO_PGM

Pragmatic general multicast

IPPROTO_L2TP

Level 2 tunneling protocol

IPPROTO_SCTP

Stream control transmission protocol

IPPROTO_RAW

Raw IP packets

Additional protocols are supported through the use of raw sockets.

A WSK application specifies a protocol when it calls the **WskSocket** function or the **WskSocketConnect** function to create a new socket.

A WSK application also specifies a protocol (as the *Level* parameter) when it calls the **WskControlSocket** function to set or retrieve transport protocol level or network protocol level socket options.

Combinations

IPv6 supports the following combinations of socket types and protocols for each WSK socket category:

Basic Sockets SOCK_STREAM + IPPROTO_TCP SOCK_DGRAM + IPPROTO_UDP SOCK_RAW + IPPROTO_*Xxx* Listening Sockets SOCK_STREAM + IPPROTO_TCP

Datagram Sockets SOCK_DGRAM + IPPROTO_UDP SOCK_RAW + IPPROTO_*Xxx* Connection-Oriented Sockets SOCK_STREAM + IPPROTO_TCP

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SIO_ADDRESS_LIST_CHANGE

Article • 03/03/2023

The SIO_ADDRESS_LIST_CHANGE socket I/O control operation notifies a WSK application when there has been a change to the list of local transport addresses for a socket's address family. This socket I/O control operation applies to all socket types.

To be notified when there has been a change to the list of local transport addresses for a socket's address family, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_ADDRESS_LIST_CHANGE
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to be notified of a change to the list of local transport addresses for a socket's address family. The WSK subsystem queues the IRP and returns STATUS_PENDING. If a change is made to the list of local transport addresses for the socket's address family, the WSK subsystem completes the IRP. When the IRP's completion routine is called, the WSK application can use the SIO_ADDRESS_LIST_QUERY socket I/O control operation to query the new list of local transport addresses for the socket's address family.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SIO_ADDRESS_LIST_QUERY

Article • 03/03/2023

The SIO_ADDRESS_LIST_QUERY socket I/O control operation allows a WSK application to query the current list of local transport addresses for a socket's address family. This socket I/O control operation applies to all socket types.

To query the current list of local transport addresses for a socket's address family, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskIoctl**
ControlCode	SIO_ADDRESS_LIST_QUERY
Level	0
InputSize	0
InputBuffer	NULL
OutputSize	The size, in bytes, of the buffer that is pointed to by the *OutputBuffer* parameter.
OutputBuffer	A pointer to the buffer that receives the current list of local transport addresses. The size of the buffer is specified in the *OutputSize* parameter.
OutputSizeReturned	A pointer to a ULONG-typed variable that receives the number of bytes of data that is copied into the buffer that is pointed to by the *OutputBuffer* parameter.

A WSK application does not specify a pointer to an IRP when calling the **WskControlSocket** function to query the current list of local transport addresses for a socket's address family.

If the call to the **WskControlSocket** function succeeds, the output buffer contains a SOCKET_ADDRESS_LIST structure followed by the SOCKADDR structures for each of the local transport addresses for the socket's address family.

If the **WskControlSocket** function returns STATUS_BUFFER_OVERFLOW, the variable that is pointed to by the *OutputSizeReturned* parameter contains the output buffer size, in bytes, that is required to contain the complete list of local transport addresses for the socket's address family.

The SIO_ADDRESS_LIST_CHANGE socket I/O control operation allows a WSK application to be notified when there has been a change to the list of local transport addresses for a socket's address family.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_BROADCAST

Article • 12/15/2021

The state of the SO_BROADCAST socket option determines whether broadcast messages can be transmitted over a datagram socket. This socket option applies only to datagram sockets.

To set the state of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_BROADCAST
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the value for the new state of the socket option: 0: Do not allow broadcast messages 1: Allow broadcast messages
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the state of this socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**
ControlCode	SO_BROADCAST
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL

Parameter	Value
OutputSize	sizeof(ULONG)
OutputBuffer	A pointer to a ULONG-typed variable that receives the value of the state of the socket option: 0: Broadcast messages are not allowed 1: Broadcast messages are allowed
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the state of the SO_BROADCAST socket option.

The default state of this socket option is that broadcast messages are not allowed.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_CONDITIONAL_ACCEPT

Article • 12/15/2021

The state of the SO_CONDITIONAL_ACCEPT socket option determines whether conditional acceptance mode is enabled on a listening socket. This socket option applies only to listening sockets.

If a WSK application sets this socket option, it must do so before the listening socket is bound to a local transport address.

To set the state of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_CONDITIONAL_ACCEPT
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the value for the new state of the socket option: 0: Disable conditional accept mode 1: Enable conditional accept mode
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the state of this socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**
ControlCode	SO_CONDITIONAL_ACCEPT
Level	SOL_SOCKET

Parameter	Value
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(ULONG)
OutputBuffer	A pointer to a ULONG-typed variable that receives the value of the state of the socket option: 0: Conditional accept mode is disabled 1: Conditional accept mode is enabled
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the state of the SO_CONDITIONAL_ACCEPT socket option.

The default state of this socket option is that conditional accept mode is disabled.

Some transport protocols might not support conditional accept mode on listening sockets.

For more information about conditionally accepting incoming connections, see Listening for and Accepting Incoming Connections.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_EXCLUSIVEADDRUSE

Article • 12/15/2021

The state of the SO_EXCLUSIVEADDRUSE socket option determines whether the local transport address to which a socket will be bound is exclusively reserved for use by that socket. This socket option applies only to listening sockets, datagram sockets, and connection-oriented sockets.

If a WSK application sets this socket option, it must do so before the socket is bound to a local transport address.

To set the state of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_EXCLUSIVEADDRUSE
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the value for the new state of the socket option: 0: Disable exclusive use of the local transport address 1: Enable exclusive use of the local transport address
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the state of this socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**

Parameter	Value
ControlCode	SO_EXCLUSIVEADDRUSE
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(ULONG)
OutputBuffer	A pointer to a ULONG-typed variable that receives the value of the state of the socket option: 0: Exclusive use of the local transport address is disabled 1: Exclusive use of the local transport address is enabled
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the state of the SO_EXCLUSIVEADDRUSE socket option.

The default state of this socket option is that exclusive use of the local transport address is disabled.

For more information about using the SO_EXCLUSIVEADDRUSE socket option and its impact on the sharing of local transport addresses between sockets, see Sharing Transport Addresses.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_KEEPALIVE

Article • 12/15/2021

The state of the SO_KEEPALIVE socket option determines whether keep-alive packets are sent on a connection-oriented socket. This socket option applies only to listening sockets and connection-oriented sockets.

To set the state of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_KEEPALIVE
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the value for the new state of the socket option: • 0: Disable sending keep-alive packets • 1: Enable sending keep-alive packets
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the state of this socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**
ControlCode	SO_KEEPALIVE
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL

Parameter	Value
OutputSize	sizeof(ULONG)
OutputBuffer	A pointer to a ULONG-typed variable that receives the value of the state of the socket option: - 0: Sending keep-alive packets is disabled - 1: Sending keep-alive packets is enabled
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the state of the SO_KEEPALIVE socket option.

The default state of this socket option is that sending keep-alive packets is disabled.

If this socket option is enabled on a listening socket, all incoming connections that are accepted on that listening socket have this socket option enabled by default. A WSK application can call the **WskControlSocket** function on an accepted socket to override the state of this socket option that was inherited from the listening socket.

Keep-alive packets are sent by the underlying network transport. Not all network transports support sending keep-alive packets.

For more information about using keep-alive packets, see *RFC 1122*, section 4.2.3.6, "TCP Keep-Alives".

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_RCVBUF

Article • 12/15/2021

The SO_RCVBUF socket option determines the size of a socket's receive buffer that is used by the underlying transport. This socket option applies only to listening sockets, datagram sockets, and connection-oriented sockets.

To set the value of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_RCVBUF
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the new size of the socket's receive buffer
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the value of the SO_RCVBUF socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**
ControlCode	SO_RCVBUF
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(ULONG)

Parameter	Value
OutputBuffer	A pointer to a ULONG-typed variable that receives the current size of the socket's receive buffer
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the value of the SO_RCVBUF socket option.

The default size of a socket's receive buffer is transport-specific. Some transports might not support this socket option.

If this socket option is set on a listening socket, all incoming connections that are accepted on that listening socket have their receive buffer set to the same size that is specified for the listening socket. A WSK application can call the **WskControlSocket** function on an accepted socket to override the size of the receive buffer that was inherited from the listening socket.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

SO_REUSEADDR

Article • 12/15/2021

The state of the SO_REUSEADDR socket option determines whether the local transport address to which a socket will be bound is always shared with other sockets. This socket option applies only to listening sockets, datagram sockets, and connection-oriented sockets.

If a WSK application sets this socket option, it must do so before the socket is bound to a local transport address.

To set the state of this socket option, a WSK application calls the WskControlSocket function with the following parameters.

Parameter	Value
RequestType	**WskSetOption**
ControlCode	SO_REUSEADDR
Level	SOL_SOCKET
InputSize	sizeof(ULONG)
InputBuffer	A pointer to a ULONG-typed variable that contains the value for the new state of the socket option: • 0: Disable always sharing the local transport address • 1: Enable always sharing the local transport address
OutputSize	0
OutputBuffer	NULL
OutputSizeReturned	NULL

To retrieve the state of this socket option, a WSK application calls the **WskControlSocket** function with the following parameters.

Parameter	Value
RequestType	**WskGetOption**

Parameter	Value
ControlCode	SO_REUSEADDR
Level	SOL_SOCKET
InputSize	0
InputBuffer	NULL
OutputSize	sizeof(ULONG)
OutputBuffer	A pointer to a ULONG-typed variable that receives the value of the state of the socket option: • 0: Always sharing the local transport address is disabled • 1: Always sharing the local transport address is enabled
OutputSizeReturned	NULL

A WSK application must specify a pointer to an IRP when calling the **WskControlSocket** function to set or retrieve the state of the SO_REUSEADDR socket option.

The default state of this socket option is that always sharing the local transport address is disabled.

For more information about using the SO_REUSEADDR socket option and its impact on the sharing of local transport addresses between sockets, see Sharing Transport Addresses.

Requirements

Version	Available in Windows Vista and later versions of the Windows operating systems.
Header	Ws2def.h (include Wsk.h)

Network Drivers Prior to Windows Vista

Article • 12/15/2021

To access the design guide and reference topics for Windows 2000 and Windows XP network drivers, see Network Drivers Prior to Windows Vista.

Network drivers prior to Windows Vista used NDIS 5.1, which was superceded in Windows Vista and later by NDIS 6.X.
